BAP – Biodiversity Action Plan

FRDBI – Fungal Records Database of Britain & Ireland

CHEG – Clavulina, Hygrocybe, Entoloma and Geoglossom (scoring system used to ascertain importance of grassland habitats)

Executive Summary

This report was commissioned by Atkins Global on behalf of The City of London as part of an environmental impact survey, to give an appraisal and provide base line information of the larger fungi occurring in and around areas within which, in-depth dam works are to take place.

The survey was carried out from August 27th to November 22nd 2013, initially two visits per month, increasing to three visits during peak fruiting months such as October and November. The survey was carried out in the following areas

1. Upper Fairground, The Vale of Health and environs, heading east to the Hampstead Pond Chain, taking in Lime Avenue en route, heading north-west along and around the ponds. See Fig 1 & 1b.

2. The Highgate Pond Chain heading north to south, east and west of the survey boundaries, from the Stock Pond to Tennis Courts and environs. See Fig 2 & 2b

Identifications were carried out in the field and where necessary collections were made for identification by microscope. Certain 'fungi hotspots' were identified and these are discussed in results. Specimens of rare and unusual species were collected, dried, written up and deposited as voucher specimens at the Fungal Herbarium, Royal Botanic Gardens, Kew.

A total of 251 species were identified from 1,117 records. Most species were what you would expect from the particular areas surveyed and the complex of habitats therein. However the survey also revealed endangered and very rare species, such as *Russula rhodomelanea* and *Cortinarius urbicus*. These and other rare species found are discussed and pictured (in part) in results. Some of these species are red data and as such will need protection, especially if they are situated directly where dam works will have most impact, such as the Vale of Health Pond east margin. Sixteen records are new to Hampstead Heath, four are new to the county of Middlesex. Four red data species were recorded, all species of *Boletus*. Translocation of such species is not an option as this method has not been successfully proven. The grasslands revealed few species, yet habitat surrounding the ponds and much of the wooded area revealed healthy populations among a fairly diverse range of genera and species. These are discussed in the results and recommendations are given to encourage a future presence.

The report concludes that the surveyed areas hold a diverse range of fungal species. These are represented by most genera of the major groups of larger fungi to be expected from the complex of habitats therein. Where species have been identified as of local or national importance, from this or future surveys, these should be given protection under applicable BAP schemes. Some areas such as the eastern boundary of the Vale of Health, Pryor's Flats - Hornbeam and Lime, and a small area with Poplar trees on the north west corner of the East Heath car park, hold either very rare or red date species. Any major influence to the hydrology or any serious habitat destruction as a result of the dam works will affect, if not destroy the larger fungi communities in those areas, impact has to be kept to a minimum to safeguard these habitats. Translocation of any of the red data or rare species is not recommended or really an option as this is at present an unsuccessfully proven method.

REPORT ON THE FUNGI OF HAMPSTEAD HEATH (In Part) SURVEY CARRIED OUT FROM AUGUST 27TH TO NOVEMBER 22ND 2013. BY ANDY OVERALL

Flat 2, 39 North End Road, Golders Green, London NW11 7RJ

1. Introduction & Historical context

Even though this survey concentrated on particular areas considered to be effected by the dam works, namely the Hampstead and Highgate pond chains, it is important to point out that any noticeable change to hydrology will in turn ultimately affect the whole of the Heath's larger fungi. Therefore it is important to have this section of the report cover the Heath as a whole.

Hampstead Heath is situated in North West London and comprises 275 hectares, 230 of which lie within the London Borough of Camden and 45 hectares within the Borough of Barnet. Roads and buildings encompass the Heath. It is currently managed by The City of London.

This is the first, official baseline fungi survey to have been carried out on the Heath.

1.1 Historically Hampstead Heath has had to endure a fair amount of disturbance during its long 500-year history, most notably from the impact of the two world wars, during which large areas were used for allotments, military use and disposal of rubble. Sand and gravel were heavily extracted from the Heath's higher elevations, in areas such as Sandy Heath. Natural heath land became eroded over the years, as has any acid grassland, with only pockets of each still surviving as a reminder of the past. Woodland only began to return when grazing was halted during the past century. All of these changes would have had an influence/impact on the fungi present on the Heath today.

All mature Elms trees were lost to Dutch elm disease during the 1970's and many trees were destroyed and decimated by the 1987 and 1990 storms. Importantly, 800 veteran trees have now been identified and young trees are planted every year, along with the creation of wild flower meadows. Dead wood, fallen or standing is now left in situ, something that didn't happen following the 1987 storm. There are more than 30 significant ponds and a sphagnum bog, a rarity in London. Between 1997 and 2013 as leader of the London Fungus Group I have recorded over 500 species of larger fungi from across the Heath, including Kenwood. Now the Heath is a very popular public green space that comes with heavy footfall around which traffic passes, bringing with it its own pollution issues through which trees and fungi will suffer alike.

1.2 Current Status

Hampstead Heath as a whole, excluding the area known as Kenwood, which is owned and managed by English Heritage, has been designated a Site of Metropolitan Importance for Nature Conservation. Green Flag awards have been given since the inception of the award.

Past, present and future surveys on the natural fabric of the Heath should eventually combine to reveal for some areas a statutory designation.

ii

2.0 The Fungal Modes & The Habitat

In order to obtain nutrients, larger fungi are Mycorrhizal, Saprophytic or Parasitic in nature; the latter two modes are combined with some species.

Mushrooms and toadstools can either be called fruitbodies or sporocarps; the main part of the fungus is within the given substrate and is called the mycelium. The mycelium, consisting of cottony, thread-like elements known as hyphae, absorbs nutrients to enable it to produce mushrooms and toadstools. There are three main ways in which fungi obtain nutrients.

Mycorrhizal fungi form a mutual symbiosis via the roots of various trees and shrubs with which they exchange nutrients. These are very important fungi that help maintain healthy trees and woodland. Most of our native trees have this association with fungi; naturalized trees such as Horse Chestnut and Sycamore do not.

Saprophytic fungi feed on dead and dying matter, helping to break down matter and release nutrients back into the soil.

Parasitic fungi take and give nothing in return. Some of these fungi are very destructive, such as *Armillaria mellea* - Honey Fungus or *Meripilus giganteus* the Giant Polypore, the former is parasitic and then saprobic on its host.

The survey was carried in the following areas

1. Upper Fairground, the Vale of Health and environs, heading east to the Hampstead pond chain, taking in Lime Avenue en route, heading north-west along and around the ponds. See figs 1 & 1b

The Upper Fairground situated at around 440ft above sea level and the slightly lower Vale of Health survey areas are partly on free draining Bagshot Sands and as the land slopes eastwards on the survey, the sandy soil merges with clay to form claygate beds; this is where water is forced upward resulting in natural springs. Heading further eastwards the soil becomes London Clay. Trees on this section of the survey are mainly broadleaved deciduous trees, dominated by Oak with Quercus robur being the dominant species there also a few Fagus silvaticus, Beech, Tilia sp, Lime, and Populus sp, Poplar are present, mixed with Sycamore, Horse Chestnut and Plane trees. Making up the shrub layer in the woodland areas are trees such as Silver Birch, Betula pendula, Willow, Salix sp, Corylus avellana, Hazel, Alder, Alnus glutinosa, False Acacia, Robinia pseudoacacia, Ash-Fraxinus excelsior and Sambucus nigra, Elder. There are also a small number of conifer trees, including Pinus sylvestris. Ground flora is mainly dominated by Bramble. Plenty of dead wood, standing and fallen was in evidence.

2. The Highgate Pond Chain heading north to south from Stock Pond and environs, see fig 2 & 2b

The lower Highgate Pond Chain lies predominantly on London Clay merging with claygate beds in places, rising to Bagshot Sand to the North in Highgate Town itself. Here also the trees are deciduous broadleaved trees, such as Oak, Beech, Lime, and Poplar with the understorey much the same as the Hampstead Pond Chain, that of Birch, Willow, Hazel, Ash and Elder. Again where possible, plenty of fallen and standing dead wood is left in situ.

1

3.0 Method

The survey was carried out from August 27th until November 22nd, therefore providing a good time period that covered the changing, environmental conditions. Two visits per month were allocated for the months in which fewer fungi were to be expected and three visits during October and November during which more fungi were expected to appear. The survey was carried out on a search and record basis.

Given the size of the survey areas, one visit per month was allocated to each area. During October and November when three visits per month were made, the third visit would be split between the two areas, covering all compartments of each area during the visits.

When possible, species were named in the field, if not possible, collections were made for identification by microscope. Status and nomenclature criteria used in the accompanying spreadsheet of species recorded, was based upon recent literature listed in the bibliography at the end of the report, in particular the *Checklist of British and Irish Basidiomycota* by Legon and Henrici (2005, published by Kew Gardens). Frequency was given as in the pre-mentioned publication, as Frequent, Infrequent, Occasional, Widespread, Rarely Reported, Rare or Red Data Listed. For the Boletes, reference was also made to the JNCC* 2013 pilot Red List Data List of Fungi for Great Britain: *Boletaceae*. In some instances these entries were modified with qualifiers such as Locally Common. GPS readings were taken for each rare or endangered species for their exact location. Specimens of the rare and unusual species were collected, dried, written up and deposited as voucher specimens at the Fungal Herbarium, Royal Botanic Gardens, Kew.

4

4.0 Areas of particular note & future potential

4.1. Compartment 517-521 – Vale of Health and environs

Throughout most of the survey, the western slopes of the Hampstead Pond Chain, proved to be the most prolific of the two survey areas. This is not surprising given that these slopes offer free draining, sandy soils and water runoff, a habitat which most terrestrial larger fungi of all types, will prefer, as opposed to the more clayey soils of the lower Highgate chain. Of particular interest are the margins of the Vale of Health Pond. These margins contain old specimens of Willow mixed with Birch on sandy soil and as a result, many mycorrhizal species are associating with these trees, some of which are very rare, such as *Cortinarius urbicus* and *Cortinarius tabularis* both new records to the Heath and to the county of Middlesex. Were these pond margins to be severely affected by the dam works, these and other species would undoubtedly be lost.

4.2. Comp 1,137 – Hornbeam & Lime

The Hornbeam and Lime trees lying directly north east, behind the Pryor's Flats on East Heath Road provide a good habitat for a number of mycorrhizal species. *Lactarius circellatus* pretty much restricted to its host tree, Hornbeam, (it is very occasionally found with Hazel also) was recorded here in large numbers throughout much of the survey. I have in recent years recorded *Russula pseudoaffinis* with the Lime trees of this area, a species that has only been recorded from Hampstead Heath and was new to Britain as recently as 2004. Also the uncommon *Russula farinipes* and the very rare *Inocybe appendiculata* were recorded. There are also interesting species of *Cortinarius* that sporadically fruit in this area as well as the eye catching, *Lactarius fulvissimus*. It is a heavily trodden area, which is resulting in compaction; this will have a detrimental effect on the mycelium of these fungi. Any serious impact form the dam works will only heighten the demise of these and other fungi.

4.3. All Compartments containing woodland areas

The woodland areas covered are dominated by broadleaved deciduous trees such as Oak, *Quercus robur* on acid to neutral soil and the majority of the larger fungi picked up during the survey were common, healthy populations that reflected this habitat type. There was however a few exceptions, compartment 1,153, an area of woodland much like any other in this part of the Heath, produced some very good records. It is sometimes difficult to understand why one area, much like any other, has more diverse fungi species than another. This area is in a dip just off the main path leading up to the Hockey Pitch situated just before the catchment area slightly north of the Mixed Bathing Pond. A lone Hornbeam tree stands surrounded by Oak and other trees, fruiting close to the Hornbeam were, *Russula rhodomelanea*, a red data, mycorrhizal species, new to Middlesex and the Heath, along with the uncommon Bolete, *Leccinum crocopidium* also red data* both fruiting in numbers. Other species were also thriving here, so obviously a hotspot. This area would need to be considered if it were likely that dam works were to overspill into this area.

4.4. All Grassland areas

Very few larger fungi were recorded from the grasslands within the survey areas. Mycena aetites, Mycena oliveceomarginata, Bolbitius titubans, Parasola plicatilis are all common grassland inhabiting species which were picked up on the survey. Grassland species of note such as suites of Clavulinopsis, Hygrocybe, Entoloma and Geoglossum, known as CHEG*, which are used as key indicators in grading the quality of grasslands, were not recorded during the survey. * CHEG is a scoring system that is to ascertain the importance of a given piece of grassland, the more species of the genera involved at any one time (visit) the better the grade and importance.

4.5. All compartments containing fallen or standing dead wood

This type of habitat is crucial for a succession of various types of dead wood specialists across many genera. There is plenty of this habitat type throughout the survey areas and some good records were picked up such as *Coriolopsis gallica, Lenzites betulinus, Postia subcaesia* and more. Unless removed these are unlikely to be affected by the dam works.

4.6. Compartments containing open water, ponds, river, streams or brooks.

As highlighted by The Vale of Health, these areas are of importance to fungi in that many of them will have Alder or Willow nearby as well as Oaks, all good mycorrhizal hosts, these areas among those that will be most affected by the dam works. Apart from the ponds themselves, other water courses within the survey area, such as the Hampstead Stream that runs east to west across the upper pond chain is a case in point with many different species associating with the variable trees that border it. The main ponds along the Hampstead chain revealed very little around their immediate boundaries but much of the areas are inaccessible, due to housing, private swimming or just being fenced off. Records were picked up on the outer margins of the ponds of both Hampstead and Highgate chains, important records of common mycorrhizal species, such as, Lactarius plumbeus, Amanita rubescens, Paxillus involutus, Laccaria amethystina and Laccaria laccata, Russula plumbeobrunnea, Russula atropurpurea, Russula fragilis and more. All of the pond margins of each chain will be adversely affected by the dam works, resulting in habitat damage and therefore loss of species. If the damage is light and temporary, it is possible that some species may recover from the initial impact.

5.0 Results and species of particular note.

A total of 253 species from 1,117, records were identified from the two survey areas, between August 27th and November 22nd 2013. 2013 was probably the best year for larger fungi in just under a decade and as a result a higher number of records were made. This was also borne out by the representation of most genera, spread across many different families, which would be expected from an area such as Hampstead Heath and the complex of habitats therein. Sixteen records were new to Hampstead Heath, four records were new to the County of Middlesex and four red data species were recorded, all of the Red Data Species belong to the *Boletaceae* family and were designated so in reference to the recent Joint Nature Conservancy Council publication, UK Fungi- Red Data List – *Boletaceae*.

The 'western slopes' of the Hampstead Heath pond chain, proved to be most fruitful of the survey sites, which included the Vale of Health, south and east pond margins. This comes as no surprise given that the soil in this area is sandy and free draining; most terrestrial, larger fungi prefer this habitat type. Among the species recorded here were the very rare, new site and county records, *Cortinarius urbicus* and *Cortinarius tabularis*, both of which were associating with the Willow and Birch trees on the margin of the pond.

There is distinct contrast between these upper slopes and the more clayey soils of the lower slopes of the Heath, where water is held longer, such as areas around the

Highgate Pond chain and indeed the Hampstead Pond chain, where, as result less species were recorded.

Alongside the Pryor's Flats a small group of Hornbeam and Lime trees offer hosts to a distinct variety of mycorrhizal fungi among which the Hornbeam associate *Lactarius circellatus* thrives with a healthy population. Also recorded here was the rare, *Inocybe appendiculata* and *Russula farinipes* both new records for the Heath.

At the north western corner of the East Heath car park, one of the areas likely to be affected by the dam works, there are a small group of Grey Poplar trees and associating mycorrhizally with these trees is the now Red Data listed, *Leccinum duriusculum*. Commonly known as the Grey Slate Bolete this species has recently been designated as near threatened as defined by the *IUCN. This decision was reached due to uncertainty regarding estimated populations from 97 unique georeferenced UK sites. *International Union for Conservation of Nature

Other Red Data Listed species of *Boletus* picked up during the survey are as follows; *Xerocomellus bubalinus, Xerocomellus engelii* and *Xerocomellus ripariellus.* The inclusion of these three species is due to data deficiency, as a result of having only been described during the last decade, therefore giving little time to build a decent enough picture of distribution and populations. Also recorded, *Rubinoboletus rubinus* has been proven to be vulnerable.

A record new to site and county, *Russula rhodomelanea* was recorded with Hornbeam, from a small pocket of woodland directly north east of the Mixed Bathing Pond and in close proximity, the uncommon Bolete, *Leccinum crocopidium*.

It was noted that various species of *Armillaria* including the Honey Fungus (*Armillaria mellea*) were quite rampant in parts of the survey areas, and following the high winds experienced during October many of the trees affected by this species literally snapped at the base and fell. I would recommend that if the Honey Fungus were not already under supervision that it should be kept in check. Although it is very difficult to manage I would not advocate, however, the use of any chemical substances.

Although not picked up in either of the survey areas I am aware that *Podoscypha multizonata*, does occur along the northern section of Lime Avenue and also on the northern side of the Stock Pond alongside the path. This species is especially associated with old deer parks, and generally fruits around the roots of old or veteran oak or beech trees, generally in open areas. South East England is host to 80% of the world's population of this species precisely because of the type of habitat provided by areas such as Hampstead Heath. Precisely because of this fact, those who have custody of the land have a duty to protect this species.

The grasslands were found to be generally poor for fungi, which could be due to under grazing, air pollution or the ramifications of dog fouling, all of which influence a low diversity sward and therefore a low diversity of fungi.

Most of the species recorded during the survey are Frequent, Common & Widespread across England and what you would expect from the various types of habitat that comprise the two survey areas. Some Very Rare and Nationally Important species were recorded during the survey. Some of these are covered below.

5.1 Russula rhodomelanea - TQ 27231 86358 – Deciduous Woodland

A very rare species new to site and county, mycorrhizal and associating with Carpinus betula, Hornbeam, just east of the Mixed Bathing Ponds. With only 9 records currently in the FRDBI*. * Fungi Records Database of Britain and Ireland.

Fig 4. – Russula rhodomelanea – © Andy Overall

5.2 Cortinarius urbicus -TQ 26630 86440 – Vale of Health east margin

A very rare species, new to site and county. A mycorrhizal species recorded associating with either Salix or Betula at the eastern margin of the Vale of Health Pond. Currently just 6 records on the FRDBI.

Fig.5 Cortinarius urbicus ©Andy Overall

5.2 *Inocybe appendiculata – TQ27532* 86716- Pryor's Flats-Hornbeam and Lime

A very rare species, reported from England and Scotland but unsubstantiated with voucher material, new to site and county. A mycorrhizal species with various broadleaved deciduous trees. Recorded close to both Lime and Hornbeam. Currently there are just 14 records on the FRDBI.

Fig. 6 Inocybe appendiculata - © Andy Overall

5.4 *Echinoderma echinaceum* - TQ 27474 86754 – Small Copse of Elm and Birch

A rather uncommon to rare yet widespread species with only one previous record for Middlesex from Perivale Woods in 1981. A new record for Hampstead Heath. A saprophytic species preferring rather nutrient rich soils. Recorded here among dead wood and soil in a small copse of elm and birch tree. The FRDBI currently holds 114 records.

Fig 7. Echinoderma echinaceum-©Andy Overall

5.5 Russula farinipes -TQ26907 86185 -Proyor's Flats - Hornbeam

An uncommon yet widespread species yet a new record for the Heath proper (I have only recorded this from Kenwood before now) and the first time I have seen it occur in this particular location over at least a decade. A mycorrhizal species recorded associating with Hornbeam. There are currently 318 records of this on the FRDBI with only four of those (mine) coming from Middlesex.

Fig. 8 Russula farinipes - ©Andy Overall

5.6 *Xerocomellus bubalinus* – Red Data – Data Deficient – Upper Fairground– Compartment 1,173

This species has been entered as Red Data Species due to the fact that it was described in 1991 and only recently recorded from GB in 2007 so it is listed as Data Deficient (DD) in the recent Boletaceae Red Data List produced by the JNCC. It is proving to be quite common on forays that I lead in Middlesex, so I should imagine that this status will change over the coming years. The same can be said of *Xerocomellus engelii* with regard to its red data entry and its regularity upon my foray lists but the same cannot be said of *Xerocomellus ripariellus* which is proving to be much rarer and therefore may stand as a more genuine red data candidate.

Fig. 9 Xerocomellus bubalinus - ©Andy Overall

5.7 *Leccinum duriusculum* – Red Data – Near Threatened East Heath Car Park - Poplar

This species has been included on the recent Boletaceae Red Data List as Near Threatened (NT). Its 'precautionary' inclusion has arisen from uncertainty regarding population estimates from 97 unique georeferenced sites. A very healthy population thrives amongst a small population of Poplar trees at the north-west corner of the East Heath car park. It is mycorrhizal with various Poplars and Aspen. There are currently only 254 records in the FRDBI.

Fig. 10 Leccinum duriusculum ©Andy Overall

5.8 Leccinum crocipodium - TQ 27231 86358 - Woodland

An occasional yet widespread species of least concern on the Bolete Red Data List. All the same this is a good record. In fact I have not recorded this from the Heath proper, only from Kenwood. There seemed to be a good population thriving in this area. It is a species that is mycorrhizal with Oak, Quercus sp. Currently there are 322 records on the FRDBI.

Fig.11 Leccinum crocipodium ©Andy Overall

5.9 Lactarius circellatus – Pryor's Flats - Hornbeam

An occasional yet widespread species that is mycorrhizal with Hornbeam and very occasionally Hazel. A very healthy population thrives with the Hornbeam up alongside the Pryor's Flats. It was picked up on the survey during September through to November 2013. There are currently 325 records of this on the FRDBI out of which 10 (mine) are from Middlesex and Hampstead Heath.

Fig.12 Lactarius circellatus ©Andy Overall

5.10 *Lactarius fulvissimus* – Woodland Edge – south of Vale of Health - opposite Kiddies Playground

This is a striking mycorrhizal species of 'MilkCap' with only twelve records (mine from Hampstead Heath) out of a total of 671 records on the FRDBI. It is considered by the Checklist of British & Irish Basidiomycota to be occasional and possibly only locally frequent. It is often found with the Hornbeam or Lime next to the Pryor's Flats on this occasion it was recorded from the border of the woodland just opposite the kiddies play area south of the Vale of Health Pond.

Fig.13 Lactarius fulvissimus ©Andy Overall

5.11 Pluteus umbrosus - TQ27530 86722 - Woodland on dead fallen tree

An occasional yet widespread, saprophytic species, often on very decayed and large chunks of Elm or Beech. It was difficult to ascertain exactly which tree this was growing on but I believe it was either Elm or Poplar due to the surrounding trees and other fallen trees. A beautiful species with only eleven out of 576 records on the FRDBI originating from Middlesex, nine of these are mine from the Heath.

Fig.14 Pluteus umbrosus ©Andy Overall

5.12 Ramaria stricta – Woodchip – Close to Information Centre and Staff Yard

A common to occasional, yet widespread species that was once a rather uncommon inhabitant of Beech woodland, attaching to buried Beech wood. It has in more recent years become quite common upon woodchip mulch where it can take up large swathes. Commonly known as the Upright Coral this was recorded from the woodchip/mulch on the corner of the Highgate Rd, staff yard. Very few records, twelve in fact from Middlesex, out of 913 in total on the FRDBI. 5.13 *Rubinoboletus rubinus* – TQ 26549 86698 – Red Data Vulnerable - Beech Woodland

This species is included on the recent Red Data List as vulnerable. It is mycorrhizal with either Oak or Beech. A thermophilous Bolete preferring older woodlands. This is a new record for Hampstead Heath proper, although I have recorded it from Kenwood. There are 138 records on the FRDBI with only three (mine) from Middlesex.

Fig. 15 Rubinoboletus rubinus ©Andy Overall

5.14 *Cortinarius saturninus* – TQ25410 87387 corner of Mixed Bathing Ponds, beneath Salix.

A rarely recorded yet widespread mycorrhizal species associated with a variety of deciduous trees especially Willow and Hawthorn. This record was found with a lone Willow tree situated on the north-east corner of Mixed Bathing Pond. This is only the seventh record for this species in Middlesex among 141 records for Great Britain and Ireland in the FRDBI.

Fig. 16 Cortinarius saturninus ©Andy Overall

5.14 Agrocybe cylindracea – TQ27530 86722

A saprophytic species fruiting from lesions, knot holes or rotten sections of live standing or dead fallen Poplar or Willow trees and, more rarely Elder. It often also fruits from around the base of otherwise healthy looking trees. An occasional species with a southsouth western biased, rarely reported elsewhere. There are 386 records on the FRDBI with just 28 from Middlesex, with just four, which are mine, from the Heath.

Fig. 17 Agrocybe cylindracea ©Andy Overall

5.15 Leotia lubrica – TQ25410 86397 – Edge of Hampstead Stream

A new record for site and county. Given that there are over a thousand records of this on the FRDBI it is quite remarkable that not one is from Middlesex, this being the first. This record was from the edge of the Hampstead Stream at section close to where people cross the stream. Commonly known as 'Jelly Babies' as it has a jelly like texture and no gills or tubes like the conventional mushroom types. It belongs to a different class, The Ascomycetes. 5.16 *Agaricus cappellianus* – TQ27930 86367 – At base of old Salix alongside the Highgate Pond No 1

A rarely reported species that has undergone a few name changes over the years, such as *Agaricus vaporarius* and *Agaricus subperonatus* the latter of which some authors may regard as a 'good species' its own right. This record was from around the base of one of the old Willow trees bordering the Highgate Pond 2. There are only two records from Middlesex on the FRDBI out 139 in total, both are mine and one of these is from the Lime Avenue.

Fig. 18 Agaricus cappellianus ©Andy Overall

6.0 Recommendations

6.1 Damage from Dam Works

Areas containing red data or rare species have been identified from the survey, such as the east margin of the Vale of Health Pond and woodland directly east of the Mixed Bathing Pond. It would be advisable to keep any likely disturbance to these and other areas at an absolute minimum to minimise the prospect of losing these and other important species from the Heath. Translocation of any of these species is not an option as this is has not yet been successfully proven.

6.2 Grassland

As the grassland within the survey area was generally and relatively fungi poor I would advocate more grazing across the site to help bring about a more diverse sward. This will in turn help to encourage more fungi of different genera to the grasslands. If this cannot be achieved and if not already practised, a mowing/cutting regime would be advisable during spring and early summer. The off cut should be removed. This process should continue for up to three years to allow for seeds of the ranker grasses to grow out and for other grasses to move in to form a more diverse sward.

6.3 Sycamore, Bramble & Honey Fungus

Invasive shrubs are largely well managed within the survey areas however, where they do exist, a lack of light and moisture will inhibit mycelia growth. Sycamore trees need thinning out in some areas to help create more light for native trees to prosper. Sycamore is not a mycorrhizal partner. Honey Fungus was rather rampant in parts of the survey area and will therefore need some management, but without the use of any chemical products. Clearance of bramble, for instance in areas such as around the Pine trees next to the Ice House would encourage fungi to fruit and any species that are present with these trees and other areas with large concentrations of bramble and other light omitting, water loving ground flora.

6.4 Biodiversity Action Plans

Where certain species from the park have been identified as vulnerable or endangered with reference to data from the current UK Fungi Draft Red Data List. A local or where appropriate, national Biodiversity Action Plans should be applied, if this has not already been done. This will afford further protection for the species.

7.0 Conclusion

In conclusion, the Hampstead and Highgate Pond chains appear to be well represented by most genera of the major groups of fungi to be expected from the complex of habitats therein. The upper section of the Hampstead Pond chain, The Vale of Health and environs, was by far the most productive of the survey areas, the Highgate Pond chain was generally a little poorer for larger fungi be they mycorrhizal, saprophytic or parasitic. This I would put down to soil type and topography. Larger fungi in general prefer free draining soil on land with an incline allowing water to run off, this occurs more so on the 'western slopes' than it does at the more northern side, where soils are heavier with clay, therefore holding more water. It is interesting to note the steady improvement of the larger fungi mycota; the further north-west one heads, along the survey route, the soil becomes noticeably more sandy and free draining. The same trees occur in both areas, important for the mycorrhizal fungi but less are encountered along the Highgate chain of ponds.

Particular areas of both survey areas can be identified as 'hotspots' for various types of fungi. As already pointed out, the Vale of Health and environs is one of these hotspots where many different mycorrhizal and saprobic species, from different genera, thrive. Most interestingly the eastern and southern margins of the pond provided new records for the Heath and for Middlesex, *Cortinarius urbicus* and *Cortinarius tabularis* being among them. But these areas also have many common, yet no less important mycorrhizal species, such as *Lactarius pubescens, Lactarius plumbea, Lactarius tabidus, Lactarius glyciosmus, Cortinarius hemitrichus, Amanita muscaria, Amanita fulva, Amanita rubescens* and more from different genera. Areas of the lower Highgate chain, the large Willow trees that border the west side of the Mens Swimming Pond and a small Elm and Birch copse situated at TQ 27474 86754 where the uncommon *Echinoderma echinaceum* was recorded for the first time on the Heath (see highlighted species) and only the second record for Middlesex, the first being way back in 1981 in Perivale Woods.

The wooded areas behind the Hampstead No.2 pond and the Mixed Bathing Pond both hold a diverse range of larger fungi of all types, most notably behind the Hampstead No.2 Pond, *Agaricus impudicus* and *Lactarius fulvissimus* behind the Mixed Bathing Pond, the very rare *Russula rhodomelanea* another new record for site and county was recorded alongside the uncommon *Leccinum crocipodium* in one small area comprising a lone Hornbeam tree surrounded by Oak and small Elm.

There are hotspots pocketed throughout both survey areas, highlighting that impact from the dam works must be kept at an absolute minimum to safeguard these habitats.

The grasslands were also generally disappointing for all types of fungi. It is likely that more grazing or if not already implemented, a mowing/cutting regime is needed to allow for more diverse grass species. The influence of dog fouling and atmospheric pollution would also be an influencing factor.

Standing and fallen deadwood provided some good records such as *Coriolopsis gallica* on Ash, *Rhodotus palmatus* on Elm and *Postia subcaesia* on Willow. Recommended action in this case would be to encourage more standing and fallen deadwood, wherever possible, out in the open areas of the Heath.

Collectively, these habitats, which constitute the areas surveyed, hold a diverse range of fungal species across many genera of the major fungal groups. In a number of cases some species are of local or national importance, which should be noted and afforded some protection under the applicable BAP schemes. Any major influence to the hydrology or any serious habitat destruction as a result of the dam works will affect, if not destroy the larger fungi communities in those areas, impact has to be kept to a minimum to safeguard these habitats. Translocation of any of the red data or rare species is not recommended or really an option as this is at present an unsuccessfully proven method.

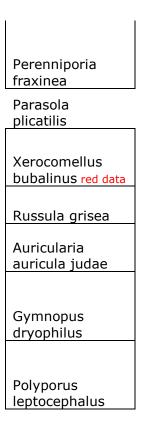

APPENDIX 1

Species lists and notes for each visit in order of date

Hampstead Heath-Dam Project Fungi Survey-Hampstead Chain 27/08/2013

Appendix 3

Acknowledgments

Thanks to the staff at Hampstead Heath especially Meg Game for her help in supplying maps and site plans.

Thanks to Mariko Parslow, Bryn Dentinger and Martyn Ainsworth at the Jodrell Centre, Kew, for putting up with and taking care of my voucher specimens at the Kew Fungal Herbarium.
