## Surface Water Discharge & Attenuation Calculations

May 2016

## 1 Introduction

The purpose of this report is to establish the pre development surface water run-off rates from an existing site, to determine the required restricted surface water run-off rates to achieve a 50% betterment of the pre development rates, assuming 30% increase for climate change, and to establish the associated attenuation volumes when restricting the post development surface water run-off.

The pre and post development areas of the site are as follows:

|                                    |   |                               |
|------------------------------------|---|-------------------------------|
| Overall Site Area                  | = | 4000m <sup>2</sup> / 0.400 ha |
| Existing Impermeable Area          | = | 1100m <sup>2</sup> / 0.110 ha |
| Existing Permeable Area            | = | 1285m <sup>2</sup> / 0.129 ha |
| Existing 'green' area of structure | = | 1610m <sup>2</sup> / 0.161 ha |
| Proposed Impermeable Area          | = | 4000m <sup>2</sup> / 0.400 ha |
| Proposed Permeable Area            | = | 0m <sup>2</sup>               |

Note for the purpose of this report and to be conservative, the proposed green / brown roofs have been ignored to be conservative.

## 2 Pre-development Surface Water Run-off Rates

In order to determine what the post development surface water run-off rates are to be, in order for the 50% betterment to be achieved, the existing / pre development surface water run-off rates are to be calculated.

The existing / pre development impermeable area is 0.11ha which is assumed to be positively drained to the local sewer network. There is also a 'green' area of 0.161 ha over a basement structure which is also assumed to drain to the local sewer network. This area is deemed to be the equivalent of a green roof.

The variables to calculate the pre development surface water run-off rates have been taken from the Flood Studies Report (FSR) and Wallingford Procedure, and have been checked against XP Solution WinDes computer software via a 'mock' drainage network (refer Appendix A).

The variables used to calculate the surface water run-off rates for the pre development site are as follows:

|                           |   |           |
|---------------------------|---|-----------|
| Existing Impermeable Area | = | 0.110 ha  |
| Existing Green Roof Area  | = | 0.161 ha  |
| M5 – 60 (mm)              | = | 20.600    |
| Ratio R                   | = | 0.437     |
| Cv (Summer)               | = | 0.750     |
| Cv (Winter)               | = | 0.840     |
| Time of Entry             | = | 5 minutes |
| Climate Change            | = | 0         |

Based on the above variables and computer software results, the pre development surface water run-off rates will be as follows:

|    |   |        |
|----|---|--------|
| Q1 | = | 16 l/s |
|----|---|--------|

|      |   |        |
|------|---|--------|
| Q30  | = | 39 l/s |
| Q100 | = | 51 l/s |

### 3 Post-development Surface Water Run-off Rates & Volumes – No Restrictions

In order to determine the impact of the development in terms of surface water run-off rates, the proposed / post development surface water run-off rates are to be calculated with no restrictions.

As stated above, the proposed / post development impermeable will over the entire site of 0.400 ha, with the two areas being 0.139 ha and 0.261 ha.

The variables to calculate the post development surface water run-off rates have also been taken from the Flood Studies Report (FSR) and Wallingford Procedure, have also been checked against XP Solution WinDes computer software via a 'mock' drainage network (refer to Appendix B)

The variables used to calculate the surface water run-off rates for the post development site are as follows:

|                             |   |           |
|-----------------------------|---|-----------|
| Proposed Impermeable Area 1 | = | 0.139 ha  |
| Proposed Impermeable Area 2 | = | 0.261 ha  |
| M5 – 60 (mm)                | = | 20.600    |
| Ratio R                     | = | 0.437     |
| Cv (Summer)                 | = | 0.750     |
| Cv (Winter)                 | = | 0.840     |
| Time of Entry               | = | 5 minutes |
| Climate Change              | = | 30%*      |

Based on the above variables and computer software results, the post development surface water run-off rates will be as follows:

|           |   |         |
|-----------|---|---------|
| Q1        | = | 59 l/s  |
| Q30       | = | 141 l/s |
| Q100 + CC | = | 231 l/s |

### 4 Required Surface Attenuation Volumes – 50% Betterment

It is proposed to restrict the post development run-off rates to 50% betterment of the pre development surface water run-off rate.

In order to ensure that the 50% betterment is achieved, the proposed / post development surface water run-off is to be restricted to 50% of the existing / pre development peak 1 in 1-year rate of 16 l/s. Therefore, the maximum surface water discharge rate from the proposed / post development site is to be 8 l/s.

It is proposed to have below and above ground structures to store the attenuated water when being restricted to the desired rate of 8 l/s. The surface water catchment area that will be associated with the below ground attenuation will be 'Area 1' with an area of 1390m<sup>2</sup> (0.139 ha) and the surface water catchment area that will be associated with the above ground attenuation will be 'Area 2' with an area of 2610m<sup>2</sup> (0.261 ha).

In order to minimise ground excavation, it is proposed to maximise the above ground attenuation volume, and therefore reducing the surface water run-off rate to as low as possible for the surface water catchment of Area 2 – 0.261ha.

The minimum restricted rate (to minimise blockage) is 3.5 l/s with an orifice size of 75mm. This therefore means that the restricted discharge rate for the two areas will be as follows:

|        |   |          |   |         |   |              |
|--------|---|----------|---|---------|---|--------------|
| Area 1 | - | 0.139 ha | - | 4.5 l/s | - | Below Ground |
| Area 2 | - | 0.261 ha | - | 3.5 l/s | - | Above Ground |

The required attenuation volumes when restricting the surface water to the above rates have been calculated via the XP Solutions software, using the variables and data set out in Sections 2 and 3 (refer to Appendix C).

The WinDes output file indicates the maximum volume of attenuation required (highlighted in red), which is the equivalent required attenuation volume.

### Area 1

The summary of the required attenuation volumes for each of the storm event for 'Area 1' (area of 0.139ha restricted to 4.5 l/s) are as follows:

|           |   |                          |
|-----------|---|--------------------------|
| Q1        | = | 5.7m <sup>3</sup>        |
| Q30       | = | 22.2m <sup>3</sup>       |
| Q100 + CC | = | <b>47.5m<sup>3</sup></b> |

Note: for the purpose of the attenuation volume calculations, an attenuation structure in the form 50m<sup>3</sup> cellular tank has been used to ensure no flooding occurs in the simulation of the results, in order to gain an accurate figure of maximum volume / attenuation volume.

The flow control is also indicated as a pump, as this will ensure the results show a discharge rate (maximum outflow) of 4.5 l/s. The actual flow control is likely to be a vortex or an orifice.

### Area 2

The summary of the required attenuation volumes for each of the storm event for 'Area 2' (area of 0.261ha restricted to 3.5 l/s) are as follows:

|           |   |                           |
|-----------|---|---------------------------|
| Q1        | = | 17.2m <sup>3</sup>        |
| Q30       | = | 58.4m <sup>3</sup>        |
| Q100 + CC | = | <b>117.5m<sup>3</sup></b> |

Note: for the purpose of the attenuation volume calculations, an attenuation structure in the form 120m<sup>3</sup> cellular tank has been used to ensure no flooding occurs in the simulation of the results, in order to gain an accurate figure of maximum volume / attenuation volume.

The flow control is also indicated as a pump, as this will ensure the results show a discharge rate (maximum outflow) of 3.5 l/s. The actual flow control is likely to be a vortex or an orifice.

Due to the layout of the building, no flooding can be controlled at the surface for up to the 1 in 100-year (inc climate change) storm event. Therefore, the above and below ground attenuation structures are to be sized to accommodate the require volume for up to the 1 in 100-year (inc climate change) storm event.

## 5 Surface Water Discharge Rate & Attenuation Summary

|                                             |   |                   |
|---------------------------------------------|---|-------------------|
| Total Restricted Surface Water Run-Off Rate | - | 8 l/s             |
| Total Surface Water Attenuation Volume      | - | 166m <sup>3</sup> |
| Below Ground Attenuation Volume             | - | 48m <sup>3</sup>  |

## 6 Surface Water Run-off with Foul Water Discharge

The peak foul water discharge from the development has been calculated to be 9.7 l/s. This figure is to be included in the proposed surface water discharge rate in order to establish the total combined discharge rate from the site.

The total combined discharge rates from the site for each of the storm events (assuming peak foul discharge during peak storm events) will be 17.27 l/s (8 l/s + 9.27 l/s).

This rate is greater than the pre development 1 in 1-year surface water run-off rate of 1.7 l/s, but is a 55% betterment of the pre development the 1 in 30-year surface water run-off rate, and a 65% betterment of the pre development the 1 in 100-year surface water run-off.

The likelihood of the peak foul water discharge occurring at the same time as the peak surface water run-off rates for each storm event is deemed to be low.

This with the 50% betterment being achieved during the extreme storm events means that the restricted surface water run-off rate of 8 l/s is acceptable.

## 7 Thames Water

During previous correspondence with Thames Water, completed by BDP on behalf of the Client, Thames Water have confirmed acceptance of peak discharge rates of 9.27l/s and 23.5;/s for foul and surface water respectively. Noting the final designed peak leaves are lower than these and together with the above, the proposed is deemed acceptable.
