Table of Contents

1. Introduction

The site is located on the west side of Gordon Street and consists of an urban setting constrained by a row of houses to the South (No.26/27/28/29 Gordon Street), the ACBE building to the West and Bloomsbury Theatre to the North.

The proposed development is a multi-storey building with a two-storey basement approximately 9.5 meters deep.

It is intended that an 880mm diameter secant piled retaining wall will support the sides of the excavation. This will be installed first followed by the bulk excavation. The excavation of the basement will be carried out in stages with three levels of temporary props. Once the excavation has been completed a thick slab will be cast to permanently prop the base of the retaining wall. The construction will then progress upwards with the permanent lining walls and floor slabs installed at B1 and ground, each slab propping the secant piled wall in the permanent condition. The superstructure will then be erected once sub ground structure is constructed.

Ground conditions comprise of made ground overlying River Terrace gravel and stiff London clay. The clay is homogenous, therefore it is assumed to behave in an undrained manner during the excavation period and in a drained manner in the long term.

Following the CIRIA C580 Guide tables to assign the category wall, it has been specified the wall is geotechnical Category 2 (Figure 2.4). Category 2 walls comprise conventional structures with no abnormal risks or unusual or exceptionally difficult ground or loading conditions.

The ground movements arising depend upon the ground conditions, the construction duration, methods used and the quality of workmanship

This report will concentrate on predicting the horizontal and vertical ground movements of the wall installation and soil excavation under adjacent structures using the procedure outlined in CIRIA guide C580.

2. Ground movement due to secant piled wall installation

Sequential construction of piles to form a wall causes the ground to move and to take up support in adjacent ground or on the back of an adjacent pile. Movements are therefore confined to local areas around the piles.

Ground surface settlements are greatest at the face of the wall and reduce to zero at a lateral distance corresponding to approximately 1 to 2 times the wall depth behind the wall. Vibrations caused by boring or piling may have caused densification of the coarse grained soils close to the piles.

Figures 2.8a and 2.8b in CIRIA C580 have been used to estimate the ground movements when installing the secant piled retaining wall in stiff clay (a for horizontal and b for vertical movement).

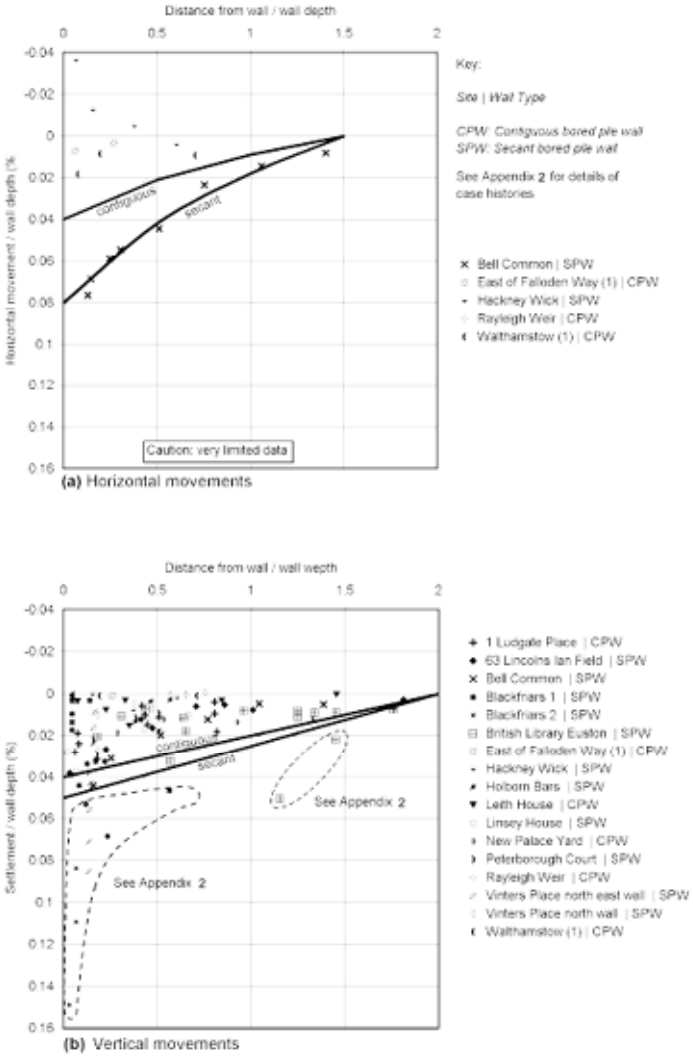

Figure 2.8 *Ground surface movements due to bored pile wall installation in stiff clay*

Figure 1 - Figures 2.8a and 2.8b from CIRIA C580

The calculations of the predicted installation ground movement are shown in Appendix A. Calculations have been made on each condition around the perimeter of the excavation, a total of 8 different sections, as shown in figure 2 below.

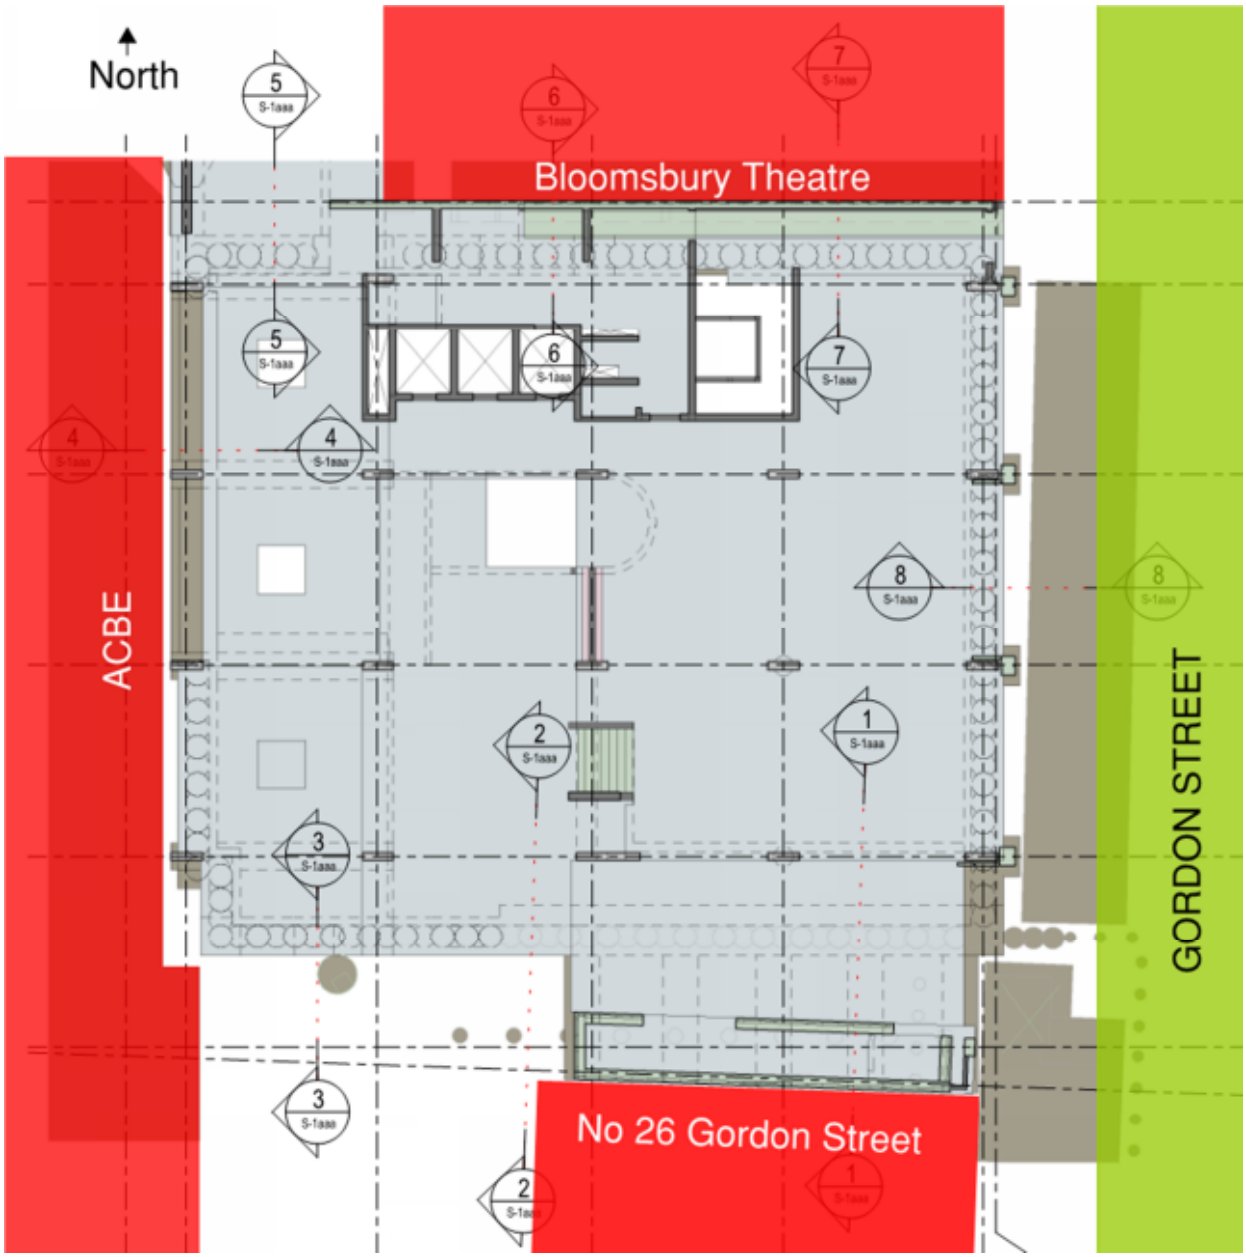

Figure 2 - Site with surrounding buildings and sections where ground movement has been calculated

3. Ground movements arising from excavation in front of wall

Movements induced by the excavation are made up of the response to the removal of lateral support to the sides of the wall and vertical load at the base of the excavation.

Figure 3 below shows typical movement patterns of the soil after excavation, the horizontal and vertical movements in the soil. The magnitude of the vertical movement depends on the plan and depth of the excavation and ground stratigraphy.

The construction of the retaining wall in this project has been taken as a high support stiffness being a propped secant pile retaining wall (Carder, Table 2.3 CIRIA C580).

From previous cases, the magnitude of horizontal wall deflection is almost totally dependent on the effectiveness of the support system.

The initial deflection, which takes place as the wall cantilevers after an initial excavation and before the first prop is installed, can, on occasions, be the largest component of the overall wall deflection. It is also the form of displacement most likely to cause damage to nearby structures. The early installation of a stiff first prop with a shallow first-stage excavation is one of the best ways to reduce wall deflections. Preloading the supports help to limit movements, and also could be obtained by using pre-stressed anchors.

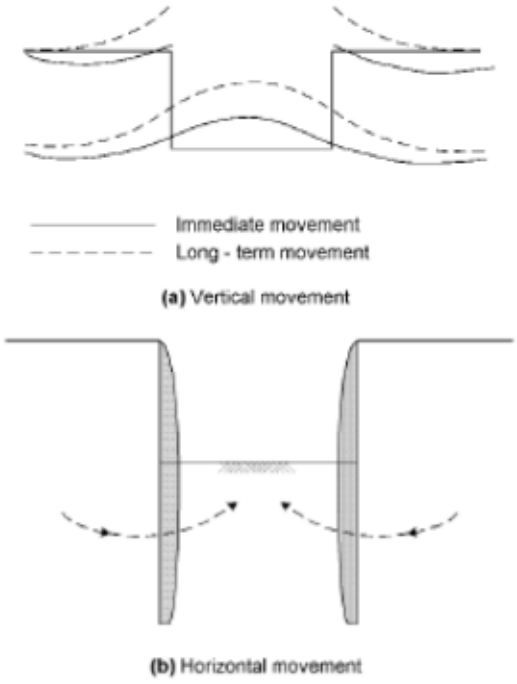

Figure 2.10 *Typical ground movement pattern associated with excavation stress relief*

Figure 3 - Figure 2.10 from CIRIA C580

4. Ground movements due to retaining wall deflection

At this stage the deflection of the piled wall has been assessed using the method described in CIRIA C580. At a later design stage the piling contractor will undertake a retaining wall analysis using WALLAP software or similar.

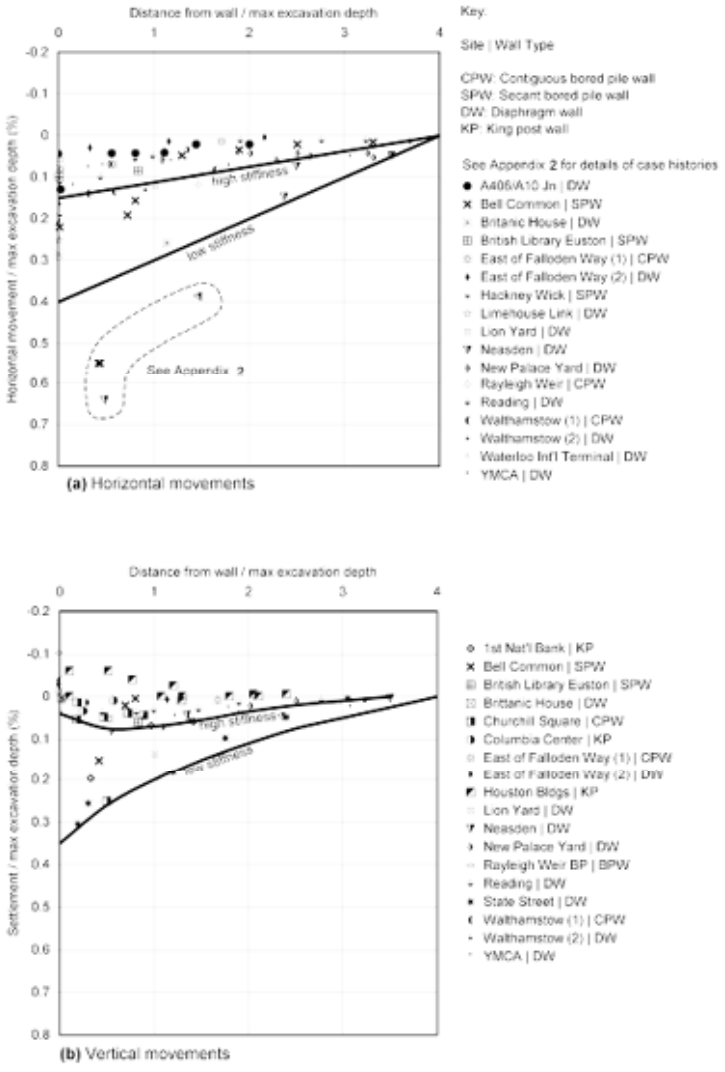

Figure 2.11 *Ground surface movements due to excavation in front of wall in stiff clay*

Figure 4 - Figures 2.11a and 2.11b from CIRIA C580

Figure 2.11a of CIRIA C580 has been used to determine the horizontal ground movement on the back of the wall due to the basement excavation in front of it. Figure 2.11b has been used to calculate the corresponding vertical movement. The results of the calculations around the perimeter of the basement are summarised in Appendix A.

5. Control of Ground Movement

The calculations of the ground movement to the back of the retaining wall around the perimeter of the basement have been undertaken with the methodology described in CIRIA C580. Graphs showing the predicted ground vertical movement resulting from the piled installation, basement excavation and a combination of both have been plotted for each section considered and included in appendix A, together with the sample of the excel spreadsheet used to plot the movement curves in the worst situation.

Some measures can be adopted to minimise ground movements around and beneath the excavation. These are summarised below:

- Good workmanship is essential. Supports should be installed tight to the wall. The prop, and any packing between the prop and waling, should not rely on friction or adhesion between the prop end and waling to hold it in place
- The wall should have adequate embedment in stiff strata for satisfactory vertical and lateral stability
- Minimise the first-stage excavation and install the first (stiff) support as early as possible in the construction sequence
- Minimise the extent of the dig beyond the proposed support levels
- Minimise delays to the construction of the wall and its support system
- Prevent deterioration of lateral support from a clay berm by blinding it or covering it with a waterproof membrane to maintain the berm's natural moisture content
- Avoid over-excavation
- Minimise removal of fines during dewatering
- Minimise drawdown outside excavation

At locations where such movements are critically important, appropriate instrumentation should be installed and the ground movements monitored. It is crucial to show good workmanship and effective control of construction operation to minimise ground movements as this is usually the reason for larger magnitudes of ground movements than predicted.

6. Building Damage Assessment

The calculated ground movement have been used to assess potential 'damage categories' that may apply to neighbouring properties due to the proposed basement construction, as per CIRIA C580 section 2.5.4. The methodology proposed by *Burland and Wroth* and later supplemented by the work of *Boscardin and Cording* has been used, as described in CIRIA C580.

General damage categories are summarised in figure 5 below:

Table 2.5 *Classification of visible damage to walls (after Burland et al, 1977, Boscardin and Cording, 1989; and Burland, 2001)*

Category of damage	Description of typical damage (ease of repair is underlined)	Approximate crack width (mm)	Limiting tensile strain ε_{lim} (per cent)
0 Negligible	Hairline cracks of less than about 0.1 mm are classed as negligible.	< 0.1	0.0–0.05
1 Very slight	Fine cracks that can easily be treated during normal decoration. Perhaps isolated slight fracture in building. Cracks in external brickwork visible on inspection.	< 1	0.05–0.075
2 Slight	Cracks easily filled. Redecoration probably required. Several slight fractures showing inside of building. Cracks are visible externally and some repointing may be required externally to ensure weathertightness. Doors and windows may stick slightly.	< 5	0.075–0.15
3 Moderate	The cracks require some opening up and can be patched by a mason. Recurrent cracks can be masked by suitable linings. Repointing of external brickwork and possibly a small amount of brickwork to be replaced. Doors and windows sticking. Service pipes may fracture. Weathertightness often impaired.	5–15 or a number of cracks > 3	0.15–0.3
4 Severe	Extensive repair work involving breaking-out and replacing sections of walls, especially over doors and windows. Windows and frames distorted, floor sloping noticeably. Walls leaning or bulging noticeably, some loss of bearing in beams. Service pipes disrupted.	15–25 but also depends on number of cracks	> 0.3
5 Very severe	This requires a major repair involving partial or complete rebuilding. Beams lose bearings, walls lean badly and require shoring. Windows broken with distortion. Danger of instability.	usually > 25 but depends on number of cracks.	

Notes

1. In assessing the degree of damage, account must be taken of its location in the building or structure.
2. Crack width is only one aspect of damage and should not be used on its own as a direct measure of it.

Figure 5 - Table 2.5 from CIRIA C580

For the critical neighbouring developments the combined impact of ground movement due to secant piled wall deflection and installation have been combined to determine the overall ground movement and impact on adjacent properties due to the construction of the basement.

The method for calculating the deflection ratios for the structures of No. 26 Gordon Street, Bloomsbury and ACBE are represented graphically in design calculations in Appendix A. The deflection ratio is calculated by using the relationship between the ground displacements and the perpendicular length of the adjacent structure. The lateral movements are considered to dissipate from a maximum at point of excavation to zero at a distance equivalent to 1.5 to 3 times the pile depth. Differential movements taken at footing levels across the span of adjacent structure are used to calculate lateral strain when considering the structure width.

The predicted ground movement and damage assessment at each boundary has been assessed; see Appendix A, with a worse case of a damage category 2 indicating that only slight damage to the neighbouring properties is expected.

APPENDICES

APPENDIX A

Short Term Heave and Long Term Heave Calculations

In the short term PDISP model the removal of the 10m of soil is modeled. In the long term the weight of the building is added as an equivalent raft at 2/3 the length of the preliminary piles. The weight of the building was taken as 85.8MN or 110kPa over the raft area.

The stiffness and Poisson's ratios used are as follows:

Made Ground : 10MPa and w4'=0.2
River Terrace : Deposits: 50MPa and w4'=0.2

London Clay: Burland and Kalra (1986) where Eu = 10 +5.2z and E' = 7.5 + 3.9z
where w4 =0.5 and w4'=0.2

Lambeth Group (top) : Eu = 550 p' assuming a K0 of 1 and E' = 0.8 Eu
Lambeth Group (bottom): Eu = 1100 p' and E' = 0.8 Eu
where w4 =0.5 and w4'=0.2

Thanet Sands : E' =900 p'

A rigid boundary was taken at -21mOD and it was assumed that the groundwater was hydrostatic from +24mOD.

It can be seen that time dependent movements outside the excavation are small.

Excluding the effect of installation of the wall, movements occur outside an excavation in stiff clay due to horizontal stress relief (the bowing out of the wall) and vertical stress relief (at the bottom of the excavation). The CIRIA C580 curve for "ground surface movements– due to excavation in front of wall in stiff clay" accounts for the short term components of both of these stress reliefs and was derived from a database of observed settlements with the installation effects removed.

In this case the retaining wall will act as stiff box and will tend to restrain any time dependent heave to inside the excavation. It is also worth noting that elastic analyses tend to overestimate the extent and magnitude of movement beyond the loaded/unloaded area. This is based on the small strain studies by Jardine et al (1986). This combined with reductions in effective stress adjacent to the excavations would indicate there would be very little change in settlements in the long term.

The use of the XDISP C580s curves should be sufficient for this building damage assessment. However if the PDISP movements are considered, the time dependent movements which are around 10mm (heave) would only serve to negate the short term settlements predicted by C580.

Analysis Options

Analysis: Boussinesq
Global Poisson's ratio: 0.20
Maximum allowable ratio between values of E: 1.5
Horizontal rigid boundary level: -21.00 [m OD]
Displacements at area centroids calculated.

RESULTS FOR GRIDS

Analysis: Boussinesq
Global Poisson's ratio: 0.20
Horizontal rigid boundary level: -21.00 [m OD]

The maximum displacement difference between
Boussinesq method (-2.080mm) and Mindlin method (1.166mm)
occurs at point X=0.0m Y=0.0m Level -1.371mOD and is 3.246mm
