

3 Screening

The London Borough of Camden guidelines suggest that any development proposal that includes a subterranean basement should be screened to determine whether or not a full Basement Impact Assessment is required. A number of screening tools are included in the Arup document and the following table uses these to assess the Surface Water flow.

| Question | Response for 32 Glenilla Road |
|--|---|
| 1: Is the site within the catchment of the ponds on Hampstead Heath | No. The Site lies to the south of the Hampstead Heath Ponds catchment area. |
| 2: As part of the proposed site drainage, will surface water flows (e.g. volume of rainfall and peak run-off) be materially changed from the existing route? | No. The area of hardstanding will remain the same and therefore the flow rates will not be changed. Where possible the proposed drainage will be connected to the existing on site drainage, mimicking the existing conditions. Where new drainage is required it will reflect the existing connections. |
| 3: Will the proposed basement development result in a change in the proportion of hard surfaced / paved external areas? | No. The current building occupies the entire site and the proposed building will also reflect this. |
| 4: Will the proposed basement result in changes to the profile of the inflows (instantaneous and long-term) of surface water being received by adjacent properties or downstream watercourses? | The existing building covers the entire site area. Surface water from the building currently drains to the public sewers. The proposed surface water drainage will mimic existing conditions. The site is underlain by London Clay which has very poor infiltration properties and therefore restrict the flow of groundwater. Therefore, the proposed basement will have a negligible effect on the local hydrogeology. |
| 5: Will the proposed basement result in changes to the quality of surface water being received by adjacent properties or downstream watercourses? | No. There are no changes in the quality of surface water, as the proposed redevelopment will not change the use of the site and there will be no below ground structures (such as piles) with the sensitive groundwater zones that could have the potential to affect the quality of groundwater. |
| 6: Is the site in an area known to be at risk from Surface water flooding, such as South Hampstead, West Hampstead, Gospel Oak and King's Cross, or is it at risk from flooding, for example because | Based on the Environment Agency flood map, the site is at risk of surface water flooding. Flood mitigation measures should be implemented to reduce the flood risk to the new basement. |
| the proposed basement is below the static water level of a nearby surface water feature? | The site is located in Flood Zone 1, with no immediate risk of flooding from Rivers and Sea. |
| Teature ! | Therefore, in accordance with Camden Planning Guidance, CPG4, a site specific FRA is required to assess the flood risk to the proposed development and the risk of loss of life, and to recommend any flood mitigation measures that may be required. |

4 Scoping and Investigations

The purpose of scoping is to assess in more detail the factors to be investigated in the impact assessment. Potential consequences are assessed for each of the identified potential impact factors.

| Potential Impact | Possible Consequence |
|---|---|
| Surface water flooding on Glenilla Road | The Environment Agency's surface water Flood Map shows that there is a risk of flooding from surface water adjacent to the proposed development on Glenilla Road. The risk of surface water run-off entering the property and proposed basement will be assessed further. |

These potential impacts have been further assessed through the preparation of a Flood Risk Assessment.

5 Development Proposals

The proposed development will demolish the existing church building and build 2 independent residential properties over a similar footprint. The proposals will provide new basements for both properties.

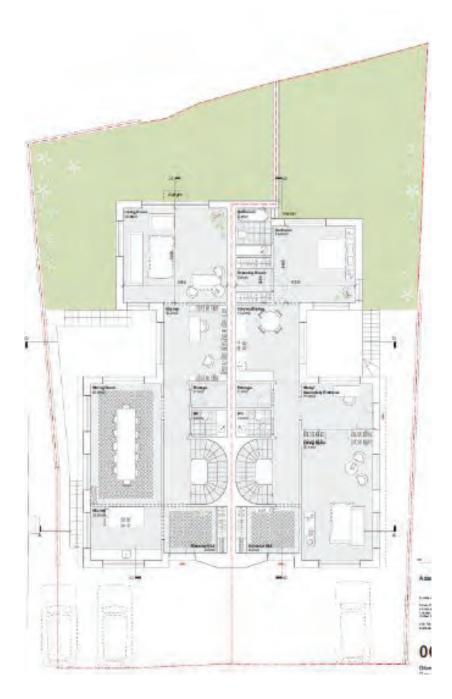

Figure 3 Proposed Development – Ground Floor

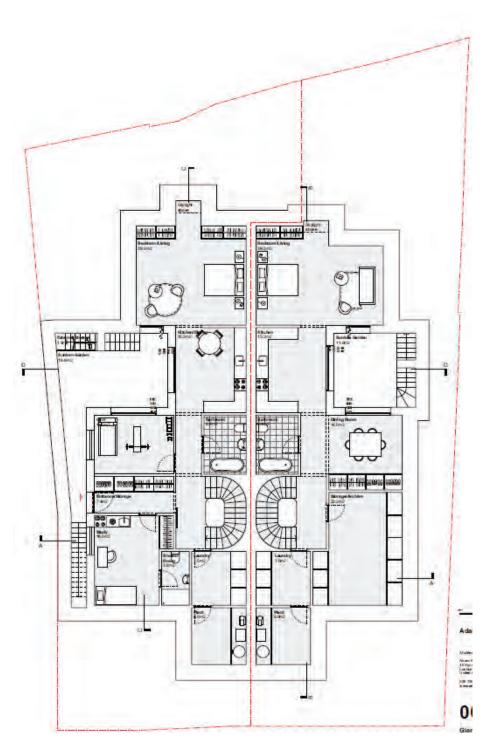

Figure 4 Proposed Development – Basement floor plan

6 Flood Risk Assessment

6.1 Flood Risk from Watercourses (Fluvial/Tidal)

The EA's indicative floodplain map shows that the site is not at risk of flooding from the River Thames or other watercourses. The map shows that the site lies in Flood Zone 1, an area with less than 0.1% annual probability of tidal and/or fluvial flooding.

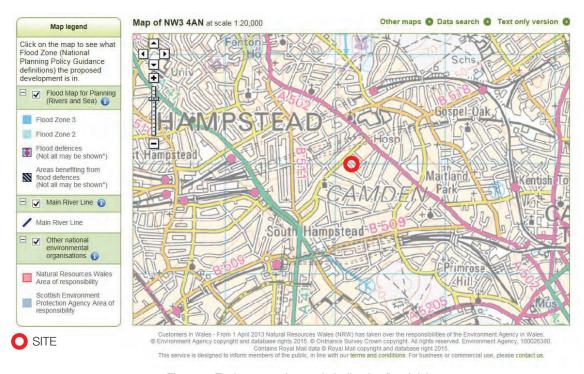

Figure 5 Environment Agency's indicative floodplain map

6.2 Flood Risk from Groundwater

A ground investigation report was not available at the time of writing, however information published by the British Geological Survey (BGS) shows that the site is underlain by London Clay Formation with no superficial deposits (Figure 6).

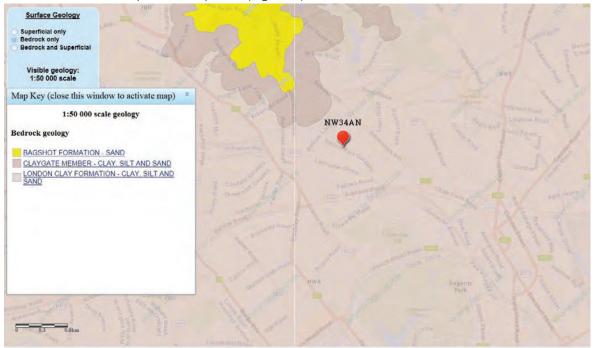

Figure 6 Local geology (extract from BGS map viewer)

This also correlates with borehole logs carried out at a nearby site on Belsize Lane to the north west of the site, where London Clay was found to be directly below the made ground. The SFRA states that no records of historical groundwater flooding have been recorded on Glenilla Road or the surrounding area. However, as the development proposals include a basement, it is important that groundwater levels including levels from any perched water are investigated to determine the risk of groundwater flooding.

The London Clay acts as an impermeable cap to the Chalk aquifer, preventing incidents of deep groundwater flooding. The basement should be designed and constructed to be fully waterproof for the lifetime of the development in accordance with current best practice and standards. This will eliminate the flood risk from groundwater to the proposed development. Therefore, the flood risk from groundwater to and from the proposed development is considered low.

The EA have defined Source Protection Zones for 2000 groundwater sources such as wells, boreholes and springs used for public drinking water supply. These zones show the risk of contamination from any activities that might cause pollution in the area. The EA maps confirm that the site is not located within any groundwater Source Protection Zone (Figure 7).

Figure 7 Environment Agency's groundwater source protection zones map

There are two main water bearing aquifers in the London Basin known as the Upper and Lower Aquifers; these are separated from each other by the thick impermeable layer of London Clay. The Upper Aquifer comprises groundwater located within deposits of River Terrace Gravels and granular soils, (including the Bagshot Formation) which overlie the London Clay. The Lower Aquifer comprises groundwater within the Thanet Sand, Upnor and Chalk Formations. The British Geological Survey (BGS) shows there are no superficial deposits on the site, (this will need to be confirmed by site investigation) and the proposed development will not extend beneath the London Clay. The proposed development is therefore not expected to have an impact on any of the local aquifers. This is confirmed by Figures 8 & 9 below, taken from the EA's website, which show that the site is not located within any aquifer catchment areas. As the site is not located within any aquifer catchment areas the proposed basement will not have an impact on any below ground flow paths and therefore will not increase the risk of flooding to the surrounding areas.

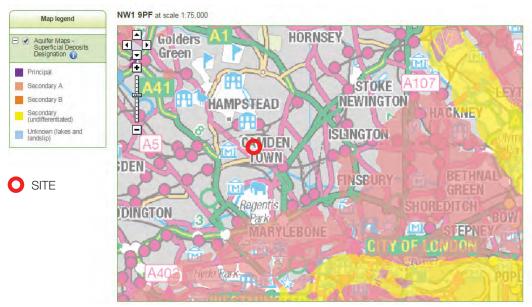

Figure 8 Environment Agency's superficial deposits aquifer map

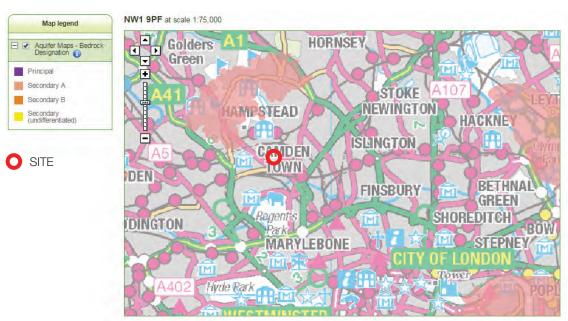

Figure 9 Environment Agency's bedrock aquifer map

6.3 Flood Risk from Surface Water and overland flows

Surface water flooding occurs when intense rainfall in unable to soak into the ground or enter a drainage system, due to blockages or the capacity of the system being exceeded. Developments with lower ground floors are naturally susceptible to this type of flooding. The EA provides an indicative map which highlights areas that are at risk of surface water flooding. Figure 10 shows that there is a "Medium" risk of flooding from surface water in Glenilla Road in the area adjacent to the proposed development.

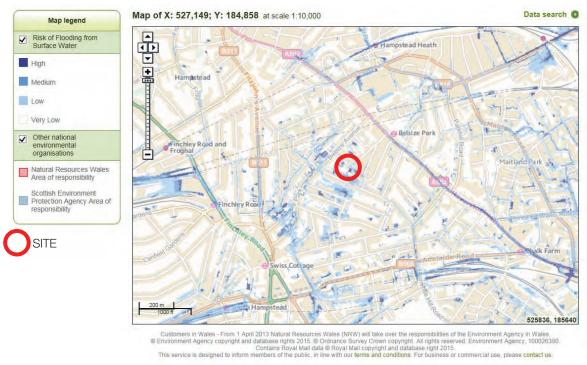

Figure 10 Environment Agency's indicative surface water flooding map

While the Environment Agency's surface water Flood Map shows that there is a risk of flooding from surface water at this location, an extended topographical survey map confirms that the site is not within a valley. This map shows a constant fall from north-west to south-east which will encourage surface water to flow downstream without flooding the local area. There is no mention of flooding incidents on Glenilla Road in the London Borough of Camden's document "Floods in Camden: Report of the Floods Scrutiny Panel". Furthermore, the ground floor level is located approximately 300mm above the lowest levels within the road.

Therefore a freeboard is provided between the access point to the basement and the potential flowing water level in the road. It is recommended the top step within the garden area which leads to the basement level to be raised in comparison with the external levels. This will discourage overland flows from entering the new lightwell and basement courtyard.

7 Run-off Assessment

In accordance with the EA's guidelines, Building Regulations and Water Authorities advice, the preferred means of surface water drainage for any new development is into a suitable soakaway or infiltration drainage system. Sustainable drainage systems (SUDS) can reduce the impact of urbanisation on watercourse flows, ensure the protection and enhancement of water quality and encourage recharge of groundwater in a manner that mimics nature. If drainage to an infiltration system proved to be an unsuitable option for a site then drainage to a watercourse must be assessed. Drainage to the public sewers can be considered only when all other alternative options are not suitable.

Drainage to infiltration systems is not a suitable option considering that there is no available land on site to accommodate such systems and the site is underlain by impermeable London Clay. Infiltration systems must be located at least 5m away from any structure. There are also no suitable watercourses in the vicinity of the site and therefore drainage to the public sewers is the only available option.

The NPPF and the EA require the surface water arising from a developed site to mimic the surface water flows arising from the site prior to the proposed development. The proposed development will not add impermeable areas on site and therefore will not increase the peak run-off rates. However, the London Plan requires new developments to limit surface water run-off to Greenfield rates; therefore attenuation must be considered.

The Greenfield run-off rate for the site was estimated using the Greenfield Run-off estimator tool (uksuds.com, please refer to separate Drainage Report) using the BFI specified from FEH data. The site was considered holistically because the site area for the estimator tool is 0.1ha. The 1 in 100 year Greenfield run-off rate can be calculated by multiplying the 100 year growth curve factor by Q_{bar} :

 $Q_{100GF} = 3.19 \times 0.30 = 0.96 \text{ l/sec}$

In accordance with best practice guidelines surface water should be attenuated to no less than 5l/sec, as low flow rates require small diameter flow control devices which are more likely to suffer from blockages. Therefore surface water from each property will be attenuated to 5l/sec. This will ensure that the two drainage systems (one for each property) are separate. The house owners will be responsible to maintain their drainage and SUDS. The storage volume required to attenuate to 5l/sec for the 1 in 100 year plus 30% (climate change) storm event is shown in the table below (please refer to separate Drainage Report for preliminary calculations).

| | House 32a | House 32b |
|--------------------|-------------------|---------------------|
| Attenuation volume | 18 m ³ | 15.3 m ³ |

8 Conclusions

- The site is located in Flood Zone 1 "areas with little or no potential risk of flooding (annual probability less than 0.1% for fluvial flooding), which are already developed." Therefore there is no risk of flooding from rivers and/or the sea. Proposed developments in these areas have no restrictions provided that the surface water drainage proposals will not increase the flood risk to the site or the surrounding areas.
- The site is at low risk of flooding from rising groundwater; however groundwater levels should be confirmed at site investigation. Engineering techniques such as drainage cavity systems and waterproofing should be considered during the detailed design.
- There is a low risk of surface water flooding as there is a constant fall away from the property along Glenilla Road.
- Surface water will be attenuated to 5l/sec for each property benefiting the public sewers which are currently receiving unrestricted run-off rates from the existing development.
- The proposed development has an acceptable flood risk within the terms and requirements of the NPPF and accompanying technical guidance.

24357 / Drainage Strategy

1 Introduction

Price & Myers have been commissioned to formulate the Drainage Strategy to support the Basement Impact Assessment for the proposed redevelopment of 32 Glenilla Road.

This report sets out the strategy for the drainage design for the proposed redevelopment of 32 Glenilla Road in Camden, London, to determine the possible options for foul and surface water drainage. The report will also assess the impact (if any) of the proposed development on the public sewers and the surrounding properties. Infiltration is not expected to be suitable, considering the proposed building occupies the 80 % of the site and the site is underlain by London Clay, therefore attenuation will be prioritized prior to discharge to the public sewer. Discharging foul water drainage to the public sewers will be prioritised in accordance with Building Regulations Part H.

The site is located on Glenilla Road in the London Borough of Camden (Figure 1). The site is bound by Glenilla Road to the north and existing residential properties to the east, south and west. The site is currently occupied by a single-storey derelict church hall. The topographical survey drawing (Appendix A) shows that the site is generally flat with levels varying across the site from approximately 61.80mAOD on the northern boundary to 61.60m AOD on the southern boundary. The site postcode is NW3 4AN and the grid reference is 527153E, 184858N.

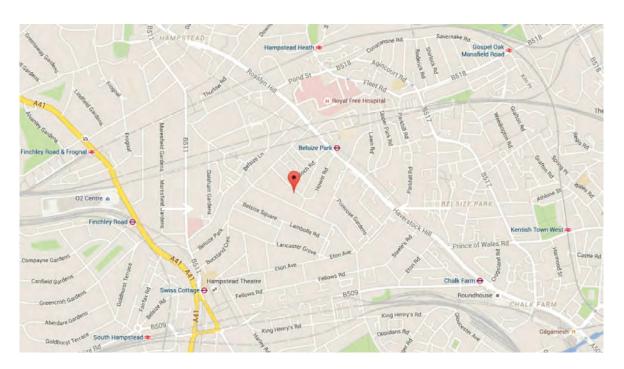

Figure 1 Site Location (Google Maps)

2 Development Proposals

The proposed development will demolish the existing church building and build 2 independent residential properties within an extended site boundary. The proposals will provide new basements for both properties.

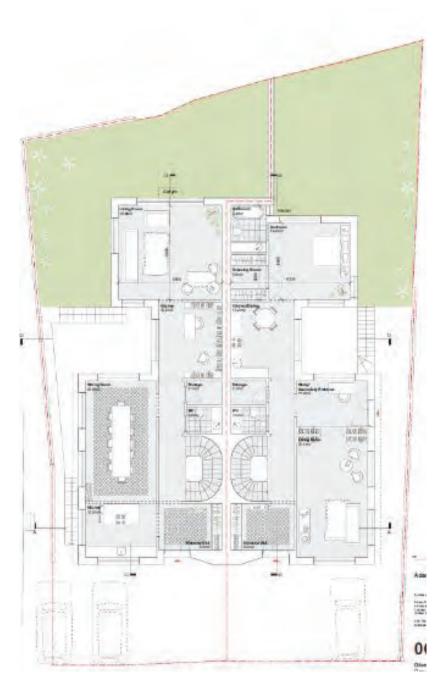

Figure 2 Proposed Development - Ground floor plan

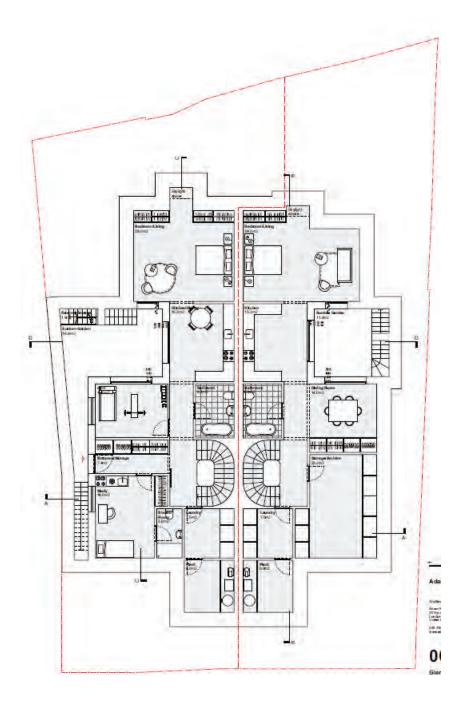

Figure 3 Proposed Development – Basement floor plan

3 Existing Drainage

At present the site area is approximately 80% impermeable. The majority of the site is occupied by the derelict church hall with some areas of soft landscaping around the perimeter. Thames Water sewer records show that there is a 381mm diameter combined sewer running north-west to south-east along Glenilla Road. There is also an adopted lateral drain running from 34 Glenilla Road (see Figure 4). The existing site boundary of No.32 will be extended to include the adopted lateral drain and Thames water manhole 181A. The owner of No.34 is a partner in the proposed development and will own House 32a, therefore the drainage strategy will seek to reuse the existing lateral drain connection to the Thames Water sewer.

Figure 4 Existing Public Sewers (Thames Water)

The existing run-off rate for the 1 in 100 years storm event was calculated based on the modified rational method:

 $Q = 2.78 \times A \times i$ (where "A" is the catchment area in Hectares and "i" is the rainfall intensity in mm/hours).

 $Q = 2.78 \times 0.053 \times 107.5 = 15.8 \text{ l/sec.}$

The church building is unoccupied at present and therefore doesn't generate any foul water flows. When the church was operational, peak foul water flows were estimated to be approximately 2.8 l/s based on a conservative assumption of the presence of a kitchenette and toilet facilities.

4 Proposed Surface Water Drainage

In accordance with the Environment Agency guidelines, Building Regulations and Water Authorities advice, the preferred means of surface water drainage for any new development is into a suitable soakaway or infiltration drainage system. Sustainable drainage systems (SUDS) can reduce the impact of urbanisation on watercourse flows, ensure the protection and enhancement of water quality and encourage recharge of groundwater in a manner that mimics nature. If drainage to an infiltration system proved to be an unsuitable option for a site then drainage to a watercourse must be assessed. Drainage to the public sewers can be considered only when all other alternative options are not suitable.

Drainage to infiltration systems is not a suitable option considering that there is no available land on site to accommodate such systems. Infiltration systems must be located at least 5m away from any structure. There are also no watercourses in the vicinity of the site and therefore drainage to the public sewers is the only available option.

The National Planning Policy Framework NPPF, the Environment Agency (EA) and Thames Water (TW) require the surface water arising from a developed site to mimic the surface water flows arising from the site prior to the proposed development. The proposed development will not add impermeable areas on site and therefore will not increase the peak run-off rates. However, the London Plan requires attenuation to Greenfield run-off rates from new developments. Therefore, attenuation must be considered.

The Greenfield run-off rate for the site was estimated using the Greenfield run-off estimator tool with the BFI specified from FEH data (uksuds.com, Appendix B). The 1 in 100 year Greenfield run-off rate can be calculated by multiplying the 100 year growth curve factor by Q_{bar} :

$$Q_{100GF} = 3.19 \times 0.30 = 0.96 \text{ l/sec}$$

Part H of the Building Regulations states that the smallest below ground pipe should be of 75mm diameter. Therefore the flow control device will use a 75mm diameter vortex control to reduce the risk of blockages. This was found to be 2.5 l/s. Therefore, surface water from each development site will be restricted to 2.5 l/sec.

The drainage strategy will provide independent drainage networks for each property, so that they can be adequately maintained by the owner. The surface flows will be restricted to 2.5 l/sec from each property via attenuation tanks. The storage volume required to attenuate to 2.5 l/sec for the 1 in 100 year plus 30% (climate change) storm event is shown in the Table 1 below (refer to Appendix B for preliminary calculations).

| | House 32a | House 32b |
|--------------------|-----------|---------------------|
| Site area | 0.018ha | 0.021ha |
| Attenuation volume | 18 m³ | 15.3 m ³ |

Table 1 Attenuation storage requirements

A SUDS Maintenance programme for the proposed development has been has been set out in Table 2 below.

SuDS Maintenance Programme

| SUDS Element | Attenuation Storage | | |
|--------------------|--|--------------------------|--|
| Maintenance Issues | Failure of components, blockage from debris | | |
| Maintenance Period | Maintenance Task | Frequency | |
| Regular | Inspect and identify any elements | Monthly for three | |
| | that are not operating correctly. | months, | |
| | | then six monthly | |

| | overflows and control structures | storms | |
| | to ensure they are in good | | |
| | condition and operating as | | |
| | designed. | | |

Table 2 SUDS Maintenance Programme

5 Proposed Foul Water Drainage

In accordance with the Building Regulations Part H, foul water drainage to the public sewers is the preferred option. TW's sewer records confirm that there are public sewers in this area. Thames Water approval for new connections will be required under a Section 106 agreement. The proposed peak foul rates were estimated using the discharge unit method from BS 12056-2:2000, the rates are presented in Table 3 below (refer to Appendix B for the calculations).

| | House 32a | House 32b |
|-----------------|-----------|-----------|
| Peak foul rates | 2.63 l/s | 5.56 l/s |

Table 3 Proposed peak foul water flow rates

While the proposed development will increase the foul peak run-off rate, the surface water will be reduced by approximately 10.8 l/sec. Therefore, the proposed development will reduce the combined peak run-off rate to the public sewers in comparison with the existing. Furthermore, the reduction in the surface water peak run-off rates will benefit the public sewers, as flooding in London is common during heavy rainfall events.

Non-return valves will be installed in the final manhole before leaving site to prevent flooding on site in the event of the public sewer surcharging. Gravity drainage must be prioritised with pumped foul water from the lower ground floor level only (if possible). Storage in the pumping system for 24 hours must be provided to allow for pump failures, in accordance with the Building Regulations requirements.

| Peak flow rates | Existing | Proposed | |
|-----------------|----------|----------|----------|
| reak now rates | Existing | 32a | 32b |
| Foul water | 2.8 l/s | 2.63 l/s | 5.56 l/s |
| Surface water | 15.8 l/s | 2.5 l/s | 2.5 l/s |
| TOTAL | 18.6 l/s | 13.1 | 9 l/s |

Table 4 Proposed discharge rates to public sewers

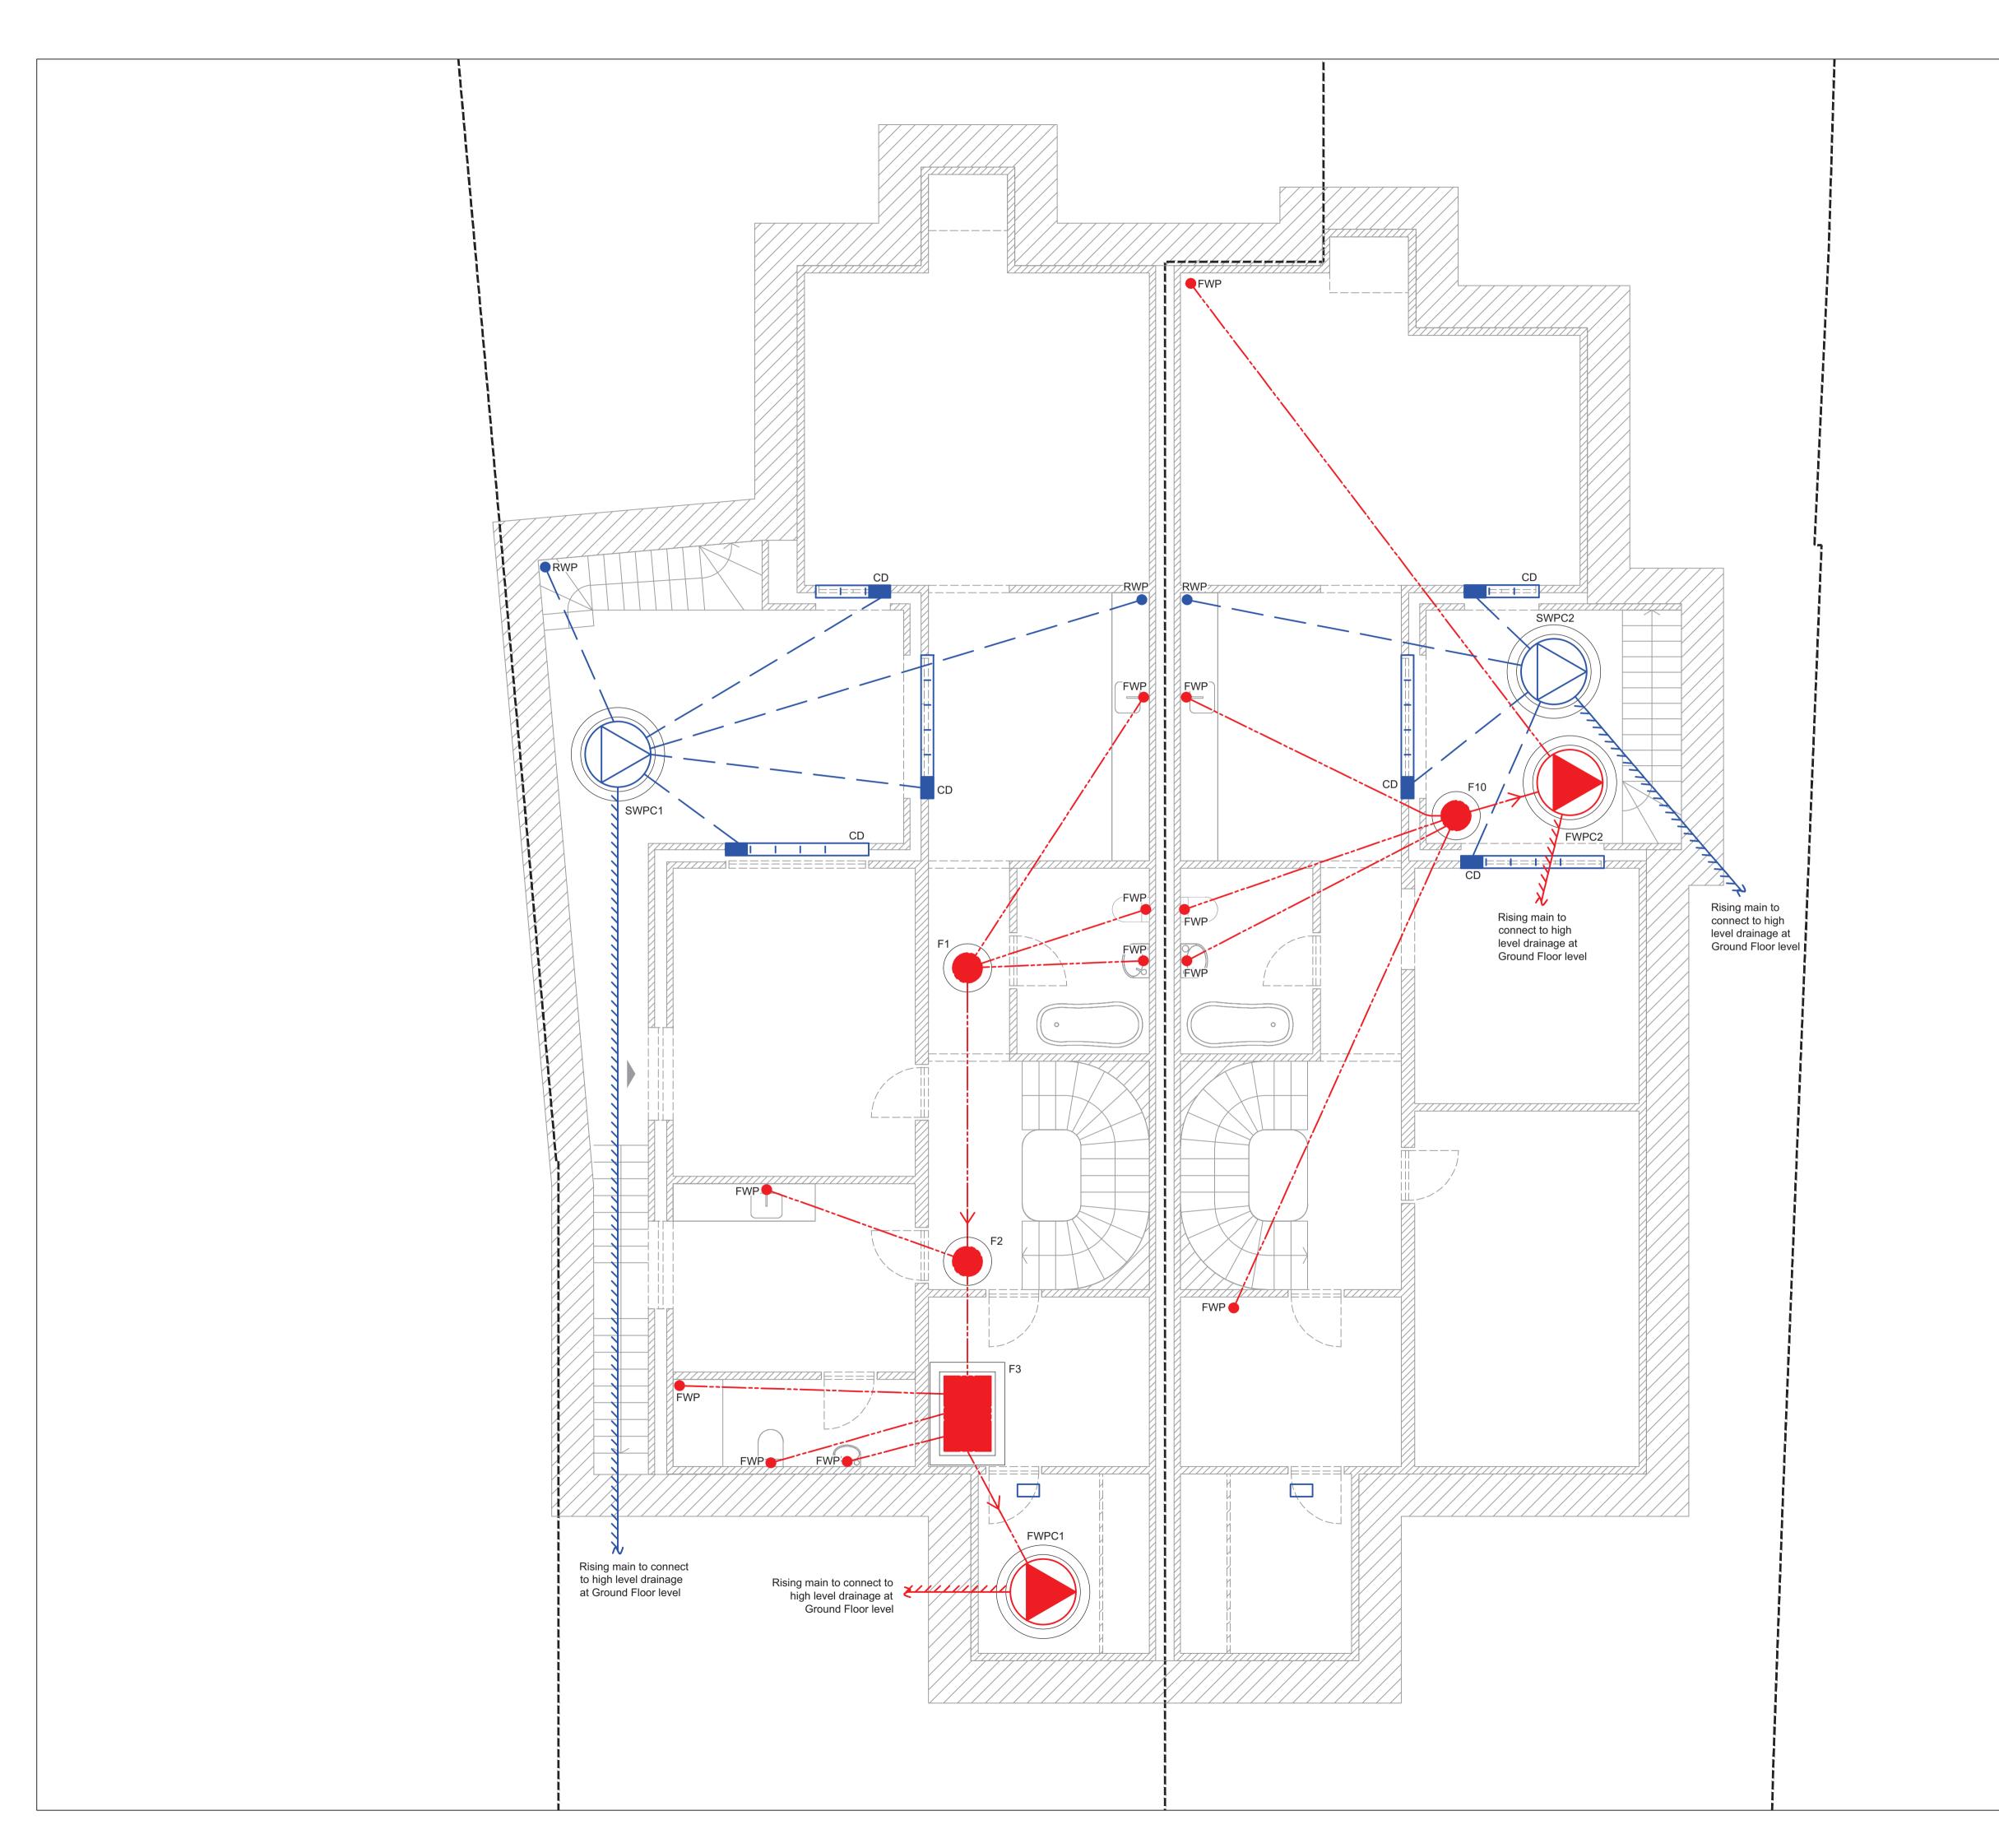

6 Conclusions

- The proposed development will reduce the impermeable areas on site and subsequently the run-off rates.
- Drainage to the ground via infiltration systems is not feasible due to the lack of available space for accommodating such systems on site.
- Surface water drainage to the public sewer is the only available option as there are no watercourses in the vicinity of the site.
- Surface water will be attenuated to 5 l/sec, benefiting the public sewers which are currently receiving unrestricted run-off rates from the existing development.
- The proposed development will increase the peak foul water flow rates from zero at present to approximately 2.6 l/s for House 32a and 5.6 l/s for House 32b. However, the proposed combined peak flow rate will be lower than the existing, benefiting the combined public sewers.
- Gravity drainage will be prioritised and protection measures must be provided where pumping is unavoidable in order to reduce the flood risk from pump failures.
- Drainage to the public sewer requires Thames Water's consent.

Analytical Report Number : 15-78181 Project / Site name: Glenilla Road

Water matrix abbreviations: Surface Water (SW) Potable Water (PW) Ground Water (GW)

| Analytical Test Name | Analytical Method Description | Analytical Method Reference | Method number | Wet / Dry Analysis | Accreditation Status |
|---|--|---|------------------|-----------------------|-------------------------|
| Boron in water | Determination of boron by acidification followed by ICP-OES. Accredited matrices: SW PW GW | In-house method based on MEWAM | L039-PL | W | ISO 17025 |
| BTEX and MTBE in water | Determination of BTEX and MTBE in water by headspace GC-MS. Accredited matrices: SW PW GW | In-house method based on USEPA8260 | L073W-PL | W | ISO 17025 |
| Cr (III) in water | In-house method by calculation from total Cr and Cr VI. | In-house method by calculation | L080-PL | W | NONE |
| Hexavalent chromium in water | Determination of hexavalent chromium in water by acidification, addition of 1,5 diphenylcarbazide followed by colorimetry. | In-house method by continuous flow analyser. Accredited Matrices SW, GW, PW. | L080-PL | W | ISO 17025 |
| Metals in water by ICP-MS (dissolved) | Determination of metals in water by acidification followed by ICP-MS. Accredited Matrices: SW, GW, PW except B=SW,GW, Hg=SW,PW, Al=SW,PW. | In-house method based on USEPA Method 6020 & 200.8 "for the determination of trace elements in water by ICP-MS. | L012-PL | W | ISO 17025 |
| Metals in water by ICP-OES (dissolved) | Determination of metals in water by acidification followed by ICP-OES. Accredited Matrices SW, GW, PW. | In-house method based on MEWAM 2006 Methods for the Determination of Metals in Soil. | L039-PL | W | ISO 17025 |
| Monohydric phenols in water | Determination of phenols in water by continuous flow analyser. Accredited matrices: SW PW GW | In-house method based on Examination of Water and Wastewater 20th Edition: Clesceri, Greenberg & Eaton (skalar) | L080-PL | W | ISO 17025 |
| pH in water | Determination of pH in water by electrometric measurement. Accredited matrices: SW PW GW | In-house method based on BS1377 Part 3, 1990, Chemical and Electrochemical Tests | L005-PL | W | ISO 17025 |
| Speciated EPA-16 PAHs in water | Determination of PAH compounds in water by extraction in dichloromethane followed by GC-MS with the use of surrogate and internal standards. Accredited matrices: SW PW GW | In-house method based on USEPA 8270 | L070-UK | W | ISO 17025 |
| Sulphate in water | Determination of sulphate in water by acidification followed by ICP-OES. Accredited matrices: SW PW GW | In-house method based on MEWAM 2006 Methods for the Determination of Metals in Soil. | L039-PL | W | ISO 17025 |
| Total cyanide in water | Determination of total cyanide by distillation followed by colorimetry. Accredited matrices: SW PW GW | In-house method based on Examination of Water and Wastewater 20th Edition: Clesceri, Greenberg & Eaton(Skalar) | L080-PL | W | ISO 17025 |
| Total Hardness of water | Determination of hardness in waters by calculation from calcium and magnesium. Accredited Matrices SW, GW, PW. | In-house method based on Examination of Water and Wastewater 20th Edition: Clesceri, Greenberg & Eaton | L045-PL | W | ISO 17025 |
| TPHCWG (Waters) | Determination of dichloromethane extractable hydrocarbons in water by GC-MS, speciation by interpretation. | In-house method | L070-UK | W | NONE |

For method numbers ending in 'UK' analysis have been carried out in our laboratory in the United Kingdom.

For method numbers ending in 'PL' analysis have been carried out in our laboratory in Poland.

Soil analytical results are expressed on a dry weight basis. Where analysis is carried out on as-received the results obtained are multiplied by a moisture correction factor that is determined gravimetrically using the moisture content which is carried out at a maximum of 30oC.

Certificate of Analysis - Asbestos Quantification

Methods:

Qualitative Analysis

The samples were analysed qualitatively for asbestos by polarising light and dispersion staining as described by the Health and Safety Executive in HSG 248.

Quantitative Analysis

"The analysis was carried out using our documented in-house method A006 based on HSE Contract Research Report No: 83/1996: Development and Validation of an analytical method to determine the amount of asbestos in soils and loose aggregates (Davies et al, 1996) and HSG 248. Our method includes initial examination of the entire representative sample, then fractionation and detailed analysis of each fraction, with quantification by hand picking and weighing.

The limit of detection (reporting limit) of this method is 0.001 %.

The method has been validated using samples of at least 100 g, results for samples smaller than this should be interpreted with caution.

Both Qualitative and Quantitative Analyses are UKAS accredited.

| Sample Number | Sample ID | Sample Depth (m) | Sample Weight (g) | Asbestos Containing Material Types Detected (ACM) | PLM Results | Asbestos by hand picking/weighing (%) | Total % Asbestos in Sample |

* These descriptions are only intended to act as a cross check if sample identities are questioned. The major constituent of the sample is intended to act with respect to MCERTS validation. The laboratory is accredited for sand, clay and loam (MCERTS) soil types. Data for unaccredited types of solid should be interpreted with care.

Stone content of a sample is calculated as the % weight of the stones not passing a 10 mm sieve. Results are not corrected for stone content.

| Total sulphate (as SO4 in soil) | Determination of total sulphate in soil by extraction with 10% HCl followed by ICP-OES. | In-house method based on BS1377 Part 3, 1990, Chemical and Electrochemical Tests | L038-PL | D | MCERTS |
| Total Sulphur in soil | Determination of total sulphur in soil by extraction with aqua-regia, potassium bromide/bromate followed by ICP-OES. | In-house method based on BS1377 Part 3, 1990, and MEWAM 2006 Methods for the Determination of Metals in Soil | L038-PL | D | NONE |
| TPHCWG (Leachates) | Determination of dichloromethane extractable hydrocarbons in leachate by GC-MS. | In-house method | L070-PL | W | NONE |
| TPHCWG (Soil) | Determination of hexane extractable hydrocarbons in soil by GC-MS/GC-FID. | In-house method | L076-PL | W | MCERTS |

For method numbers ending in 'UK' analysis have been carried out in our laboratory in the United Kingdom.

For method numbers ending in 'PL' analysis have been carried out in our laboratory in Poland.

Soil analytical results are expressed on a dry weight basis. Where analysis is carried out on as-received the results obtained are multiplied by a moisture correction factor that is determined gravimetrically using the moisture content which is carried out at a maximum of 30oC.

APPENDIX J

Contamination assessment tables

ASSESSMENT CRITERIA

Table 1 below sets out CGL's rationale for generic assessment criteria (GAC) adoption in order to evaluate risks posed to potential receptors at 32 Glenilla Road, London from identified chemical contamination. Potential receptors have been identified with reference to the Part IIA regime and associated DEFRA guidance. As with the Part IIA regime, under the planning regime all receptors (humans, controlled waters, ecology, crops/livestock and buildings) have been considered if there is the potential for them to be adversely affected by exposure to contamination. The results of the assessment for 32 Glenilla Road, London are then presented in Tables 2 to 6 of this appendix.

Table 1. Rationale for Assessment Criteria Adoption

| Source / Media | CGL's Approach & Rationale | | | | | | |
|---|---|--|--|--|--|--|--|
| Risks to Human Health (long-term chronic risks) | | | | | | | |
| Soil contaminants | Laboratory test results have been compared against Generic Assessment Criteria (GACs) derived inhouse by CGL using the Contaminated Land Exposure Assessment (CLEA) model and version 1.06 of the CLEA software. Where Soil Guideline Values (SGVs) have been published previously by the Environment Agency, the CGL GACs have updated these based on current exposure parameters (e.g. updated inhalation rates). The GACs have been generated assuming a sandy loam soil type and a Soil Organic Material of 1% for the Made Ground (measured range 0.32% to 0.59%) and 1% for the natural soils (measured 0.49% to 1.1%). In the event impacts are identified on a site above the GAC level for arsenic, cadmium, chromium VI, benzene or benzo(a)pyrene, the results have been compared to the applicable Category 4 Screening Level (C4SL) published by DEFRA to further assess risks. The exception to the above relates to lead. The SGV for lead has been withdrawn and the C4SL for lead is used by CGL directly as a first tier of assessment. The CGL GACs represent conservative screening criteria (set at acceptable or minimal risk) and have generally been calculated using the default parameters for the standard land use scenarios set out in the CLEA technical report and toxicological inputs in line with the requirements of Science Report SCO50021/SR2 and, in the case of petroleum hydrocarbons, Science Report P5-080/TR3. Where a CGL GAC has not been derived alternative assessment criteria will be sourced from current commercially-available sources (including international standards where no suitable UK assessment criteria exists). Where the dataset is of appropriate size, assessment against the applicable GAC or C4SL is carried out at the 95th percentile of the sample mean (designated US₉₈), which is considered to represent a reasonable worst-case scenario. An assessment of the normality of the data has been undertaken. Where datasets are normally distributed the one sample t-test has bee | | | | | | |
| Dissolved contaminants | Concentrations of organic constituents detected above the laboratory reporting limit in shallow groundwater or perched water have been assessed against Water Screening Values (WSVs) developed by Atkins. These WSVs assess chronic risks to human health via the indoor air inhalation pathway only. | | | | | | |
| Ground gas | Concentrations and flow rates of carbon dioxide and methane in ground gas are converted to Gas Screening Values (GSVs) in accordance with CIRIA (2007). Potential risks associated with gas chemistry are evaluated in accordance with guidance presented in CIRIA (2007), NHBC (2007), BSI (2007). | | | | | | |

Table 1 (continued). Rationale for Assessment Criteria Adoption

| Risks to Buildings & Structures | | | | | | |
|--|--|--|--|--|--|--|
| Water supply pipes | The evaluation of water supply pipe requirements at the site has been undertaken in general accordance with guidance and criteria produced by the UK Water Industry (2011). | | | | | |
| Sulfate & pH conditions • The evaluation of risks to buried concrete has followed the guidance and criteria produced by BRE (2005). | | | | | | |
| Risks to Vegeta | tion & Plants | | | | | |
| Soil contaminants | • Risks to plant growth (i.e. phytotoxicity) have been assessed for specific contaminants where the limits for phytotoxic effect proposed (e.g. by BS 3882) are significantly lower than the health GAC. | | | | | |

Table 2. Soil risks to human health (residential land use with homegrown produce) - Made Ground
