1 INTRODUCTION

1.1 Scope

Stroma Built Environment Ltd has been commissioned to undertake an air quality exposure assessment based on the potential impacts of existing and future traffic levels on a proposed development at 332 West End Lane in the London Borough of Camden. The pollutants modelled as part of this assessment are nitrogen oxides (NO_x) and particulate matter (PM₁₀).

The impacts of vehicle emissions have been assessed using the techniques detailed within Volume 11, Section 3 of the Design Manual for Roads and Bridges (DMRB)¹ and the Local Air Quality Management Technical Guidance (LAQM.TG16)². The impact of road traffic emissions will be assessed using the ADMS-Roads air dispersion model. This model has been devised by Cambridge Environmental Research Consultants (CERC) and is described as a “comprehensive tool for investigating air pollution problems due to small networks of roads”.

It should be noted that the short-term impacts of NO₂ and PM₁₀ emissions have not been modelled as dispersion models are inevitably poor at predicting short-term peaks in pollutant concentrations, which are highly variable from year to year, and from site to site. Notwithstanding this, general assumptions have been made about short term concentrations based on the modelled annual mean concentrations.

1.2 Site Description

The proposed development site is located at 332 West End Lane in the London Borough of Camden. The proposed development is a change of use on the first and second floors from a restaurant to residential use, and a loft conversion.

A location plan can be found in figure 1.

Figure 1 – Site Location Plan

¹ Design Manual for Roads and Bridges, Vol 11, Section 3, Part 1 – HA207/07, Highways Agency, May 2007

² Part IV of the Environment Act 1995, Local Air Quality Management Technical Guidance (TG16), Defra, February 2018

2 POLLUTANTS & LEGISLATION

2.1 Pollutant Overview

In most urban areas of the UK, traffic generated pollutants have become the most common pollutants. These are nitrogen dioxide (NO₂), fine particulates (PM₁₀), carbon monoxide (CO), 1,3-butadiene and benzene, as well as carbon dioxide (CO₂). This air quality assessment focuses on NO₂ and PM₁₀, as these pollutants are least likely to meet their Air Quality Strategy objectives near roads. Table 1 provides an overview of NO₂ and PM₁₀.

Table 1 – Overview of NO₂ and PM₁₀

| Pollutant | Properties | Anthropogenic Sources | Natural Sources | Potential Effects |
|--|--|--|---|--|
| Particles (PM₁₀) | Tiny particulates of solid or liquid nature suspended in the air | Road transport; Power generation plants; Production processes e.g. windblown dust | Soil erosion; Volcanoes; Forest fires; Sea salt crystals | Asthma; Lung cancer; Cardiovascular problems |
| Nitrogen Dioxide (NO₂) | Reddish-brown coloured gas with a distinct odour | Road transport; Power generation plants; Fossil fuels – extraction & distribution; Petroleum refining | No natural sources, although nitric oxide (NO) can form in soils | Pulmonary edema; Various environmental impacts e.g. acid rain |

2.2 Air Quality Strategy

The UK Government and the devolved administrations published the latest Air Quality Strategy for England, Scotland, Wales and Northern Ireland on 17 July 2007³. The Strategy provides an over-arching strategic framework for air quality management in the UK.

With regards to this assessment, the Air Quality Strategy contains national air quality standards and objectives established by the Government to protect human health. The objectives for nitrogen dioxide and particulates (PM₁₀ and PM_{2.5}) have been set, along with seven other pollutants (benzene, 1,3-butadiene, carbon monoxide, lead, PAHs, sulphur dioxide and ozone). Those which are limit values required by EU Daughter Directives on Air Quality have been transposed into UK law through the Air Quality Standards Regulations 2010 which came into force on 11th June 2010. Table 2 provides the UK Air Quality Objectives for NO₂ and PM₁₀.

³ The Air Quality Strategy for England, Scotland, Wales and Northern Ireland, Department for Environment, Food and Rural Affairs in partnership with the Scottish Executive, Welsh Assembly Government and Department of the Environment Northern Ireland, July 2007

Table 2 – UK Air Quality Objectives for Nitrogen Dioxide and Particulate Matter

| Pollutant | Objective | Concentration measured as |
|-------------------------------------|---|---------------------------|
| Nitrogen Dioxide (NO ₂) | 200µg/m ³ not to be exceeded more than 18 times a year | 1 hour mean |
| | 40µg/m ³ | Annual mean |
| Particles (PM ₁₀) | 50µg/m ³ not to be exceeded more than 35 times a year | 24 hour mean |
| | 40µg/m ³ | Annual mean |
| Particles (PM _{2.5}) | 25µg/m ³ (except Scotland) | Annual Mean |

Objectives for PM_{2.5} were also introduced by the UK Government and the Devolved Administrations in 2010. However, these are not included in Regulations as the Air Quality Strategy has adopted an “exposure reduction” approach for PM_{2.5} in order to seek a more efficient way of achieving further reductions in the health effects of air pollution by providing a driver to improve air quality everywhere in the UK rather than just in a small number of localised hotspot areas.

As defined in Table 4, background PM_{2.5} concentrations are well below the limit value of 25 µg/m³. As such, no further consideration has been given to PM_{2.5} within this assessment.

2.3 London Local Air Quality Management (LLAQM)

At the core of LAQM delivery are three pollutant objectives; these are: nitrogen dioxide (NO₂), particulate matter (PM₁₀) and sulphur dioxide (SO₂). All current Air Quality Management Areas (AQMAs) across the UK are declared for one or more of these pollutants, with NO₂ accounting for the majority. It is a statutory requirement for local authorities to regularly review and assess air quality in their area and take action to improve air quality when objectives set out in regulation cannot be met.

2.3.1 Camden Council

Camden Council has declared an Air Quality Management Areas (AQMAs) for exceedances of both the annual mean objective for nitrogen dioxide and the 24-Hour mean objective for particulate matter PM₁₀. The AQMA has been declared for the entire borough and as such the proposed development lies within the AQMA.

There are currently 187 Air Quality Focus areas which have been declared across the 33 London Boroughs. The proposed development does not lie within a focus area, however, the A41 Finchley Road within close proximity to the proposed development does lie within a focus area.

3 PLANNING POLICY & GUIDANCE

3.1 National Planning Policy & Guidance

3.1.1 National Planning Policy Framework

On a national level, air quality can be a material consideration in planning decisions. The National Planning Policy Framework (NPPF)⁴ for England, revised and released on 19th February 2019, is considered a key part of the Governments reforms to make the planning system less complex and more accessible, to protect the environment and to promote sustainable growth. The NPPF replaces the Planning Policy Statement 23 (PPS23) Planning and Pollution Control⁵.

Paragraph 170 within the NPPF states that “planning policies and decisions should contribute to and enhance the natural and local environment” and that developments “should, wherever possible, help to improve local environmental conditions such as air and water quality, taking into account relevant information such as river basin management plans”

It goes on to state in paragraph 181 that “planning policies and decisions should sustain and contribute towards compliance with relevant limit values or national objectives for pollutants, taking into account the presence of Air Quality Management Areas and Clean Air Zones, and the cumulative impacts from individual sites in local areas. Opportunities to improve air quality or mitigate impacts should be identified, such as through traffic and travel management, and green infrastructure provision and enhancement. So far as possible these opportunities should be considered at the plan-making stage, to ensure a strategic approach and limit the need for issues to be reconsidered when determining individual applications. Planning decisions should ensure that any new development in Air Quality Management Areas and Clean Air Zones is consistent with the local air quality action plan”.

3.1.2 Land-Use Planning & Development Control

In January 2017, Environmental Protection UK (EPUK) and the Institute of Air Quality Management (IAQM) produced guidance to ensure that air quality is adequately considered in the land-use planning and development control processes⁶.

The guidance document is particularly applicable to assessing the effect of changes in exposure of members of the public resulting from residential and mixed-use developments, especially those within urban areas where air quality is poorer. It is also relevant to other forms of development where a proposal could affect local air quality and for which no other guidance exists.

⁶ Land-Use Planning & Development Control: Planning for Air Quality. Guidance from Environmental Protection UK and the Institute of Air Quality Management for the consideration of air quality within the land-use planning and development control processes. EPUK & IAQM. January 2017

3.2 Regional Planning Policy

3.2.1 The Mayor's Air Quality Strategy

In October 2010, the Mayor's Air Quality Strategy⁷ was released. The strategy sets out a framework for delivering improvements to London's air quality and includes measures aimed at reducing emissions from transport, homes, offices and new developments, as well as raising awareness of air quality issues and its impact on health.

3.2.2 The London Plan

In March 2016, the updated London Plan was published by the Greater London Authority⁸. The London Plan provides an overall strategic plan for London, setting out an integrated economic, environmental, transport and social framework for the development of London over the next 20–25 years. The Plan brings together the geographic and locational aspects of the Mayor's other strategies, including a range of environmental issues such as climate change (adaptation and mitigation), air quality, noise and waste.

Policy 7.14 relates specifically to improving air quality and states the following:

"The Mayor recognises the importance of tackling air pollution and improving air quality to London's development and the health and well-being of its people. He will work with strategic partners to ensure that the spatial, climate change, transport and design policies of this plan support implementation of his Air Quality and Transport strategies to achieve reductions in pollutant emissions and minimize public exposure to pollution".

It goes on to state the following with regards to planning decisions:

"Development proposals should:

- a minimise increased exposure to existing poor air quality and make provision to address local problems of air quality (particularly within Air Quality Management Areas (AQMAs) and where development is likely to be used by large numbers of those particularly vulnerable to poor air quality, such as children or older people) such as by design solutions, buffer zones or steps to promote greater use of sustainable transport modes through travel plans (see Policy 6.3)*
- b promote sustainable design and construction to reduce emissions from the demolition and construction of buildings following the best practice guidance in the GLA and London Councils' 'The control of dust and emissions from construction and demolition'*
- c be at least 'air quality neutral' and not lead to further deterioration of existing poor air quality (such as areas designated as Air Quality Management Areas (AQMAs)).*
- d ensure that where provision needs to be made to reduce emissions from a development, this is usually made on-site. Where it can be demonstrated that on-site provision is impractical or inappropriate, and that it is possible to put in place measures having clearly demonstrated equivalent air quality benefits, planning obligations or planning conditions should be used as appropriate to ensure this, whether on a scheme by scheme basis or through joint area-based approaches*
- e where the development requires a detailed air quality assessment and biomass boilers are included, the assessment should forecast pollutant concentrations. Permission*

⁷ Clearing the Air: The Mayor's Air Quality Strategy. October 2010

⁸ The London Plan. The Spatial Development Strategy for London. Consolidated with Alterations. March 2016

should only be granted if no adverse air quality impacts from the biomass boiler are identified”.

3.2.3 Supplementary Planning Guidance (SPG)

Sustainable Design and Construction SPG

The Greater London Authority (GLA) released the “Sustainable Design and Construction” SPG in July 2014⁹. The SPG aims to support developers, local planning authorities and neighbourhoods to achieve sustainable development. It provides guidance on to how to achieve the London Plan objectives effectively, supporting the Mayor’s aims for growth, including the delivery of housing and infrastructure.

In relation to air quality the SPG provides guidance on the following key areas:

- assessment requirements;
- construction and demolition;
- design and occupation;
- air quality neutral policy for buildings and transport; and
- emissions standards for combustion plant

⁹ Sustainable Design and Construction SPG. Greater London Authority, July 2014

4 ASSESSMENT METHODOLOGY

4.1 Operational Phase

4.1.1 Modelled Scenarios

A modelled baseline year of 2017 has been used as this corresponds with the latest year of monitoring undertaken by the Council. The future year has also been chosen (2021) representing the first full year with the proposed development in place. Two scenarios have been adopted as part of the assessment. These are as follows:

- **Scenario 1** – existing levels of air quality / model verification (2017); and
- **Scenario 2** – future impact of traffic emissions on the proposed development i.e. introduction of new exposure (2021).

Predicted concentrations will be compared to the Air Quality Strategy objectives. Background pollutant concentrations and vehicle emission rates for all modelled years are based on the latest data issued by Defra. These background concentrations and emission factors are discussed further in the following sections.

4.1.2 ADMS-Roads

Modelling the impact of traffic emissions on the proposed development will be undertaken using the latest version of the ADMS-Roads model¹⁰. ADMS-Roads is significantly more advanced than that of most other air dispersion models in that it incorporates the latest understanding of the boundary layer structure, and goes beyond the simplistic Pasquill-Gifford stability categories method with explicit calculation of important parameters. The model uses advanced algorithms for the height-dependence of wind speed, turbulence and stability to produce improved predictions.

4.1.3 Emission Factors

Defra and the Devolved Administrations have provided an updated Emission Factors Toolkit (Version 9.0) which incorporates updated NO_x emissions factors and vehicle fleet information¹¹. These emission factors have been integrated into the latest ADMS-Roads modelling software. However, in order to undertake a worst-case assessment emission factors for 2017 have been used for all modelled years.

4.1.4 Traffic Data

Baseline flows along the local roads are available from the London Atmospheric Emissions Inventory (LAEI). Baseline (2013) data from the LAEI has been projected to 2017 and 2021. Projection of traffic data has been undertaken using growth factors specific to the local authority, obtained from TEMPro. The projected flow rates are provided in Table 3. It is assumed that the percentage HDV and speed will remain unchanged in future years. Where a link approaches a junction a speed of 20 kph has been modelled in order to represent queuing traffic at a junction. This is the approach recommended by the London Local Air Quality Management Technical Guidance (LLAQM.TG16) for modelling queuing traffic at junctions by way of reducing the modelled vehicle speeds.

Roads within 200m of the verification sites have been modelled for the purposes of model verification.

¹⁰ Model Version: 4.1.1.0. Interface Version 4.1.1 (18/01/2018)

¹¹ https://laqm.defra.gov.uk/documents/EFT2019_v9.0.xlsb

Table 3 – Annual Average Daily Traffic Flows, Percentage HDV and Speeds for Modelled Roads

| Link Name | AADT 2017 | AADT 2021 | HDV (%) | Speed (kph) |
|-------------------------|-----------|-----------|---------|-------------|
| West End Lane | 4,560 | 4,773 | 3.9 | 20 |
| A41 Finchley Road | 43,187 | 45,204 | 6.4 | 23 |
| B510 Fortune Green Road | 11,011 | 11,525 | 5.9 | 29 |
| Mill Lane | 13,748 | 14,390 | 6.6 | 28 |

4.2 Background Concentrations

Background NO_x, NO₂ and PM₁₀ concentrations have been obtained from Defra¹². These 1 km x 1 km grid resolution maps are derived from a base year of 2017 (for NO_x, NO₂, PM₁₀ and PM_{2.5} only), which are then projected to future years up to 2030. Background concentrations of NO₂, PM₁₀ and PM_{2.5} derived from Defra are provided in Table 4.

Table 4 – Background NO_x, NO₂, PM₁₀ and PM_{2.5} Concentrations

| Location | Pollutant | X | Y | 2017 |
|----------------------|-------------------|--------|--------|------|
| Proposed Development | NO ₂ | 525500 | 185500 | 28.3 |
| | NO _x | | | 46.2 |
| | PM ₁₀ | | | 17.9 |
| | PM _{2.5} | | | 12.2 |

In order to undertake a worst-case assessment, 2017 background concentrations have been assumed for all modelled scenarios.

4.3 Surface Roughness

A surface roughness of 1.5 metre has been used in the model. This value is provided by ADMS-Roads as a typical roughness length for large urban areas. This value has been used across the modelled domain.

4.4 Meteorological Data

Hourly sequential meteorological data from the London City Airport meteorological station has been used. Wind speed and direction data from the London City Airport meteorological station has been plotted as a wind rose in Figure 2.

¹² <https://uk-air.defra.gov.uk/data/laqm-background-maps?year=2017>

Figure 2 – Wind Speed and Direction Data, London City Airport (2017)

4.5 Model Output

4.5.1 NO_x/NO₂ Relationship

Following recent evidence that shows the proportion of primary NO₂ in vehicle exhaust has increased¹³. As such, a new NO_x to NO₂ calculator has been devised¹⁴. This new calculator has been used to determine NO₂ concentrations for this assessment, based on predicted NO_x concentrations using ADMS-Roads. Converted NO₂ concentrations are initially compared to local monitoring data in order to verify the model output. If the model performance is considered unacceptable then the NO_x concentrations are adjusted before conversion to NO₂.

¹³ Trends in Primary Nitrogen Dioxide in the UK, Air Quality Expert Group, 2007

¹⁴ http://laqm.defra.gov.uk/documents/no2tonox9_ja-forweb_june2016.xls

4.5.2 Predicted Short Term Concentrations

As discussed in the introduction, it has not been possible to model the short-term impacts of NO₂ and PM₁₀. Research undertaken in 2003¹⁵ has indicated that the hourly NO₂ objective is unlikely to be exceeded at a roadside location where the annual mean NO₂ concentration is less than 60 µg/m³.

For PM₁₀, a relationship between the annual mean and the number of 24-hour mean exceedances has been devised and is as follows:

- No. 24-hour mean exceedances = $-18.5 + 0.00145 \times \text{annual mean}^3 + (206/\text{annual mean})$

This relationship has been applied to the modelled annual mean concentrations in order to estimate the number of 24-hourly exceedances.

4.5.3 Model Verification

The monitoring sites listed in Table 5 have been used for the purposes of model verification. These are the closest monitoring sites to the proposed development.

Table 5 – Modelled Verification Locations

| Site ID | Location | X | Y | Height (m) |
|---------|-------------------|--------|--------|------------|
| CA16 | Kentish Town Road | 529010 | 185102 | 2.0 |
| CA23 | Camden Road | 529171 | 184130 | 2.0 |
| CA24 | Chetwynd Road | 528722 | 185950 | 2.0 |

4.5.4 Receptor Locations

In order to assess the potential impact of the proposed development, a number of receptors have been identified on each floor, which represent openable windows. The location of these model points, together with their height above ground level is provided in Table 6 and represented in Figures 3, 4 and 5.

Table 6 – Modelled Receptor Locations

| First floor receptors | | | |
|---------------------------|--------|--------|------------|
| Air Quality Assessment ID | X | Y | Height (m) |
| 1F_R1 | 525646 | 185317 | 1.5 |
| 1F_R2 | 525644 | 185316 | 1.5 |
| 1F_R3 | 525652 | 185303 | 1.5 |
| Second floor receptors | | | |

Figure 3 – First floor modelled receptor locations

Figure 4 – Second floor modelled receptor locations

Figure 5 – Third floor modelled receptor locations

4.6 Significance Criteria

4.6.1 Operational Phase

The significance of emissions will be determined by comparing the predicted results to the Air Pollution Exposure Criteria (APEC) detailed in the Air Quality and Planning Guidance written by the London Air Pollution Planning and the Local Environment (APPLE) working group¹⁶. The Air Pollution Exposure Criteria is considered appropriate to describe the significance of the impacts predicted, together with an indication as to the level of mitigation required in order for the development to be approved. The APEC table is provided below.

Table 7 – Air Pollution Exposure Criteria (APEC)

| APEC Category | NO₂ | PM₁₀ | Recommendations |
|----------------------|--|---|--|
| A | >5% below national annual mean objective | >5% below national annual mean objective >1-day less than national 24-hour objective | No air quality grounds for refusal; however mitigation of any emissions should be considered. |
| B | Between 5% below or above national annual mean objective | Between 5% above or below national annual mean objective Between 1-day above or below national 24-hour objective | May not be sufficient air quality grounds for refusal, however appropriate mitigation must be considered |
| C | >5% above national annual mean objective | >5% above national annual mean objective >1-day more than national 24-hour objective | Refusal on air quality grounds should be anticipated, unless the Local Authority has a specific policy enabling such land use and ensure best endeavours to reduce exposure are incorporated |

¹⁶ Air Quality and Planning Guidance, written by the London Air Pollution Planning and the Local Environment (APPLE) working group, January 2007

Figure 6 – Assessing the Significance of Air Quality Impacts of a Development Proposal

5 AIR QUALITY ASSESSMENT

5.1 Impact of Vehicle Emissions

5.1.1 Model Verification

Using the guidance provided within the London Local Air Quality Management Technical Guidance TG(16), the modelled output has been verified against the monitoring data obtained from the site listed in Table 8. The following tables provide a summary of the model verification process for NO_x/NO₂ and PM₁₀ concentrations.

Table 8 – Comparison of Modelled and Monitored NO₂ and PM₁₀ Concentrations (µg/m³)

| Verification Location | Modelled Concentration | Monitored Concentration | Difference [(modelled - monitored)/monitored] x100 |
|-----------------------|------------------------|-------------------------|--|
| CA16 | 40.7 | 74.9 | -45.7% |
| CA23 | 47.4 | 75.4 | -37.1% |
| CA24 | 37.1 | 55.0 | -32.6% |

As described in the Technical Guidance (LLAQM.TG16), in order to provide more confidence in the model predictions and the decisions based on these, the majority of results should be within ±25% (ideally ±10%) of the monitored concentrations. In order to improve the confidence in modelled concentrations across the modelled domain the model output has been adjusted. This is described further in the next section.

5.1.2 Model Adjustment

In order to undertake model adjustment, it is first necessary to derive the monitored and modelled road contributions of NO_x (excluding background). The modelled road contribution NO_x is taken directly from the ADMS-Roads output before it has been converted to NO₂ using the NO_x to NO₂ calculator described in Section 4.5.1. The NO_x to NO₂ calculator can also be used to derive monitored road contributions of NO_x from NO₂ diffusion tube results. A summary of these calculations is provided in Table 9.

Table 9 – Monitored NOx and NO₂ concentrations

| Verification Location | Monitored Total NO ₂ | Defra Background NO ₂ | Monitored road contribution NO ₂ (total – background) | Monitored road contribution NOx (total – background) | Modelled road contribution NOx (excludes background) | Ratio of monitored road contribution NOx / modelled road contribution NOx |
|-----------------------|---------------------------------|----------------------------------|--|--|--|---|
| CA16 | 74.9 | 29.5 | 45.4 | 128.8 | 25.3 | 5.08 |
| CA23 | 75.4 | 33.5 | 41.9 | 119.2 | 33.1 | 3.61 |
| CA24 | 55.0 | 29.9 | 25.1 | 62.9 | 16.0 | 3.94 |

Once the monitored and modelled road contributions of NOx (excluding background) have been derived the contributions of NOx are compared and a ratio derived. In this case it is 4.125 and is used to adjust the modelled road contribution of NOx. This is shown in Table 10.

Figure 7 – Linear Regression of Modelled and Monitored NO_s

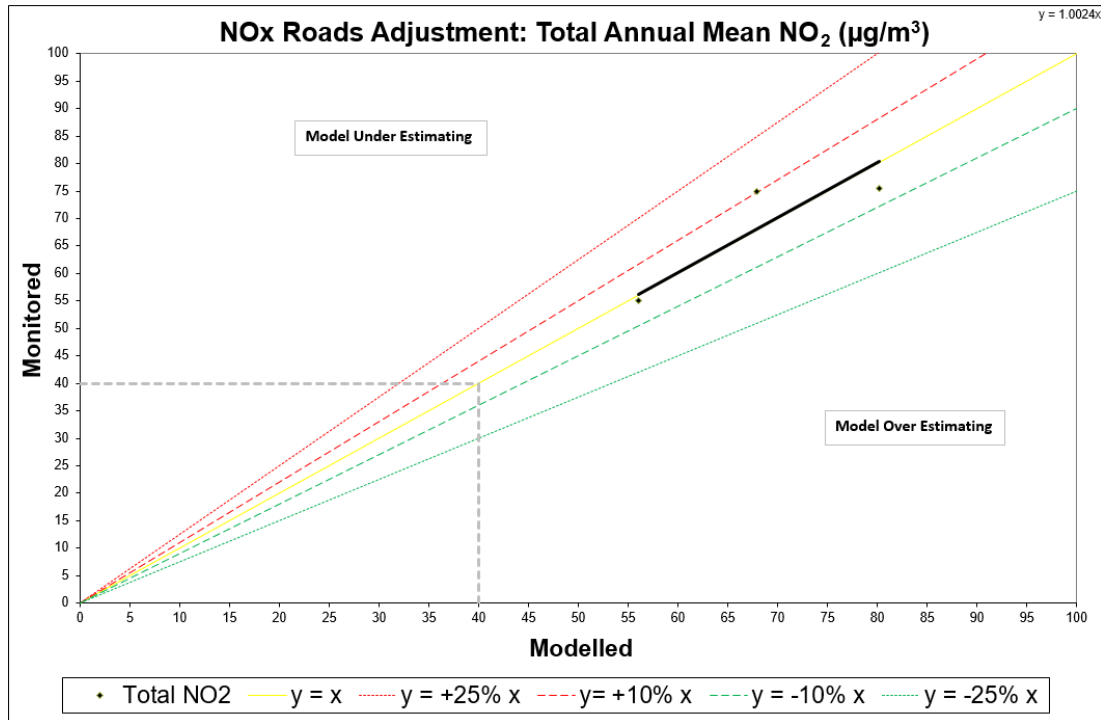

Table 10 – Adjustment of Modelled NOx Contributions

| Verification Location | Adjustment factor for modelled road contribution | Adjusted modelled road contribution NOx | Modelled total NO₂ (based on empirical NOx/NO₂ relationship) | Monitored total NO₂ | % Difference [(modelled – monitored) / monitored] x 100 |
|------------------------------|---|--|---|---------------------------------------|--|
| CA16 | 4.125 | 104.5 | 67.9 | 74.9 | -9.4% |
| CA23 | 4.125 | 136.4 | 80.3 | 75.4 | 6.4% |
| CA24 | 4.125 | 65.8 | 56.0 | 55.0 | 1.8% |

Following adjustment of the modelled NOx concentrations by a factor of 4.125 the total NO₂ concentration at the model verification location has been calculated using the method described in Section 4.5.1. The revised NO₂ concentration, shown in Table 10, indicates a more acceptable model performance when compared against the monitored NO₂ concentrations. As such, an adjustment factor of 4.125 has been applied to all modelled NOx concentrations across the model domain before conversion to NO₂.

5.1.3 Nitrogen Dioxide

Predicted annual mean concentrations for NO₂ at the proposed development in 2017 and 2021 are provided in Table 11. As mentioned in Section 4.5.1, NO₂ concentrations have been calculated from the predicted NO_x concentrations using the latest NO_x-NO₂ conversion spreadsheet available from the Air Quality Archive.

Table 11 – Comparison of Predicted Annual Mean NO₂ Concentrations (µg/m³)

| Receptor ID | 2017 | 2021 |
|-------------|------|------|
| 1F_R1 | 43.1 | 44.9 |
| 1F_R2 | 42.7 | 44.5 |
| 1F_R3 | 38.7 | 40.1 |
| 2F_R1 | 40.4 | 42.0 |
| 2F_R2 | 40.3 | 41.8 |
| 2F_R3 | 38.0 | 39.3 |
| 2F_R4 | 37.9 | 39.1 |
| 2F_R5 | 37.6 | 38.8 |
| 3F_R1 | 37.1 | 38.2 |
| 3F_R2 | 37.0 | 38.1 |
| 3F_R3 | 36.1 | 37.1 |
| 3F_R4 | 35.9 | 36.9 |
| 3F_R5 | 35.9 | 36.8 |

The ADMS predictions for annual mean NO₂ concentrations in 2017 and 2021 indicate that the annual mean objective (40 µg/m³) would not be achieved at the modelled receptor locations.

Nitrogen dioxide also has an hourly objective of 200 µg/m³ not to be exceeded more than 18 times in one year. However, the hourly mean concentration has not been calculated directly by ADMS Roads. This is as a result of an evaluation of continuous monitoring data from across the UK that revealed that the relationship between the annual mean and hourly mean NO₂ concentrations was very weak. Nonetheless, research undertaken in 2003¹⁷ has indicated that the hourly NO₂ objective is unlikely to be exceeded at a roadside location where the annual mean NO₂ concentration is less than 60 µg/m³. Given that predicted NO₂ concentration in 2017 and 2021 are well below 60 µg/m³ at the modelled receptor the likelihood of the short-term objective for NO₂ being exceeded is considered low.

¹⁷ Analysis of Relationship between 1-Hour and Annual Mean Nitrogen Dioxide at UK Roadside and Kerbside Monitoring Sites, Laxen and Marner, 2003

5.1.4 Particulate Matter

Predicted annual mean concentrations for PM₁₀ in 2017 and 2021 are provided in Table 12.

Table 12 – Predicted PM₁₀ Concentrations, Annual Mean (µg/m³)

| Receptor ID | 2017 | 2021 |
|-------------|------|------|
| 1F_R1 | 20.2 | 20.3 |
| 1F_R2 | 20.1 | 20.2 |
| 1F_R3 | 19.5 | 19.5 |
| 2F_R1 | 19.7 | 19.8 |
| 2F_R2 | 19.7 | 19.8 |
| 2F_R3 | 19.3 | 19.4 |
| 2F_R4 | 19.3 | 19.4 |
| 2F_R5 | 19.3 | 19.3 |
| 3F_R1 | 19.2 | 19.2 |
| 3F_R2 | 19.2 | 19.2 |
| 3F_R3 | 19.0 | 19.1 |
| 3F_R4 | 19.0 | 19.1 |
| 3F_R5 | 19.0 | 19.1 |

The ADMS predictions for annual mean PM₁₀ concentrations in 2017 and 2021 indicate that the annual mean objective (40 µg/m³) would be achieved at all the modelled receptor locations. In addition, the maximum number of days when PM₁₀ concentrations are more than 50 µg/m³ is 4, less than the 35 exceedances allowed in the regulations.

6 CONCLUSIONS AND RECOMMENDATIONS

6.1 Impact of Vehicle Emissions

All predicted PM₁₀ concentrations at the modelled receptor locations fall within APEC Category A, which states that there are “No air quality grounds for refusal; however mitigation of any emissions should be considered”.

The majority of the predicted concentrations of NO₂ in the base and opening model years are above the relevant objective and fall within APEC Category B and C meaning mitigation measures may need to be adopted in order to protect the future inhabitants from poor air quality. These are outlined below.

Based on the outcome of this assessment mitigation measures would be required in order to mitigate the impact of poor air quality on the future occupants of the proposed development.

The Institute of Air Quality Management (IAQM) issued a position statement in relation to the mitigation of development air quality impacts. Based on this statement, the IAQM recommends that the following basic hierarchy be used for mitigating the operational air quality impacts associated with the particular development:

1. Preference should be given to **preventing or avoiding** exposure/impacts to the pollutant in the first place by eliminating or isolating potential sources or by replacing sources or activities with alternatives;
2. **Reduction and minimisation** of exposure/impacts should next be considered, once all options for prevention/avoidance have been implemented so far as is reasonably practicable (both technically and economically). To achieve this reduction/minimisation, preference should be given first to:
 - a) mitigation measures that act on the source; before
 - b) mitigation measures that act on the pathway; which in turn should take preference over
 - c) mitigation measures at or close to the point of receptor exposure all subject to the efficacy, cost and practicability of the available solutions. In each case, measures that are designed or engineered to operate passively are preferred to active measures that require continual intervention, management or a change in people's behaviours.
3. **Off-setting** a new development's air quality impact by proportionately contributing to air quality improvements elsewhere (including those identified in air quality action plans and low emission strategies) should only be considered once the solutions for preventing/avoiding, and then for reducing/minimising, impacts have been exhausted.

Based on this hierarchy, Option 2 could be applied to the proposed development. Using Option 2, some form of mitigation would need to be implemented on all floors so that the future occupants are not reliant solely on opening windows in order to provide ventilation. This would require an additional form of ventilation; whereby clean air is drawn in naturally or mechanically and maintained thereafter.

A mechanical ventilation system that draws air in from the roof may not be considered acceptable by the Council due to predicted exceedances. Alternatively, air could be drawn in

and filtered¹⁸. Such filtration systems would “scrub” the incoming air stream of NO₂, reducing the concentrations of NO₂ to well below the air quality objective within the building. Such systems are becoming more common, particularly at city centre locations where traffic emissions make it difficult to find locations where clean air can be drawn into the property. A filtered ventilation system would also allow the inlets to be placed anywhere regardless of the predicted NO₂ concentrations, although they should ideally be placed as far away from emission sources as possible in order to reduce the burden on the filters. If such a filtration system is installed the Council will require details relating to the mechanical ventilation and air filtration systems, as well as the ongoing maintenance and cleaning of these systems.

¹⁸ Such devices include the AAC Swiftpack® with Nitrosorb® media for NO₂ and NO_x removal, or the City Breathe: Indoor Air Quality Filtration System
