

to be achieved in construction by overboring and inserting within the bore an externally slip-coated permanent steel sleeve. The overbore annulus was to be filled with bentonite/cement grout up to a level 4 m below the pile caps to give the pile lateral support, with bentonite filling only the space above.

Foundations outside ground movement areas

The piled foundations in these areas, comprising the whole of the sorting hall and about half of the welfare block, were designed as standard 600 mm friction piles of approximately 20 m length bottoming just above the Woolwich and Reading beds. The design of the ground-floor construction was carried through as determined in the feasibility study.

Ground works adjacent to the Atlantic Metals building

In the feasibility study, provision was made to minimise the effects of vertical heave on the Atlantic Metals building by introducing a contiguous piled wall just within the Granary site. While this concept was in itself satisfactory, the requirement to consider the possibility of horizontal movement in the underlying clay now gave rise to the necessity to reappraise the aptness of such a wall.

The piles, of nominal 600 mm diameter, were envisaged as being designed unrestrained laterally but, being relatively flexible, they were liable to deflect with the movement of the earth mass, thus doing little to prevent horizontal earth movement. Accordingly, the possibility of substituting for the contiguous piles with a stiffer form of construction was reexamined, but was found to be most unattractive on cost grounds.

An assessment was then made of the effect on the Atlantic Metals building of horizontal earth movement in the range of 10-20 mm, this being the anticipated deflection at surface level of the contiguous piled wall, and it was judged that the induced strains could be tolerated by the structure without distress. It was decided, therefore, to continue with the installation of the contiguous piled wall and to monitor the ground movements locally.

Ground works at the canal wall

The site investigation had revealed that the construction of the canal wall was suspect, particularly at the north end where it was for the main part founded at relatively high level. In the feasibility study the favoured solution was to bore a contiguous piled wall through the rubble berm adjacent to the canal. However, as a result of the doubts about the integrity of the wall revealed by the site investigation, the options for supporting the wall were reviewed.

Alongside the Granary the canal was unusually wide, reflecting the earlier construction of the covered loading wharf, and the idea of constructing a wall within the canal became attractive. Approaches to the canal authority were well received and, as a result, approval was given for a new permanent sheet steel wall to be constructed in the canal 1 m from the wall face over the whole length of the site and sealed back into the existing wall at each end. The sheets were to be driven by a silent and vibrationless pile-driving system and the new wall was designed to act as a cantilever founded in the London clay. At the location of the TWA sewer the much shorter piles were assumed to act as propped cantilevers supported by a walling carried to high modulus cantilever piles on each side of the sewer. In the case of the small sewer, which was only just below the bed of the canal, it was decided that the risk of the pile driving

causing collapse of the sewer was too great to accept. Accordingly, as the sewer was disused, provision was made for it to be filled with PFA grout so that the piles could subsequently be driven down to it.

A walkway was to be provided between the canal and the completed building (see Fig 10). It was to be about 2 m above the ground-floor level of the new building, and was to be retained by L-shaped free-standing reinforced concrete walls. Since the drains in this vicinity would be vulnerable to ground movement, shelves, protected by Clayboard on the underside, were designed to cantilever from the bottom of the perimeter ground beams with the drains and manholes built on them. However, that construction required deep excavations at the foot of the canal wall, so that, in certain areas, its stability was examined in relation to slip circle failure. This was viewed as being more than just a short-term problem, since the purpose of Clayboard is substantially to leave a permanent void. To restore some of the surcharge lost by forming the deep trench, it was decided to substitute a stiffer material for the Clayboard locally under pile caps and ground beams. Laboratory tests were carried out on selected grades of expanded polystyrene which showed that, once the initial yield stress of the material was overcome, creep effects became significant and compression would continue but at a reduced rate. However, the residual strength in the polystyrene was sufficient to enable a small surcharge to be generated. The presence of this material had the additional benefit of inhibiting the collection of water in the void which would have had softening effects on the clay.

The final boundary condition to be considered was that adjoining Granary Street. With the benefit of the information gained from the site investigation (i.e. the nature of the masonry, the wall thicknesses, and extent and position of foundations), it was possible to analyse the stability of the wall. On completion of the development some 2 m of fill material was required to be placed which would improve the wall stability sufficiently to enable the raking shores inserted at the time of demolition to be removed. However, as a slight movement of the wall would occur if the shores were removed, it was considered prudent to leave them in place to avoid the possibility of damage to the road and services running in it. To increase the life of the shores, which would be buried, they were to be encased in concrete.

Superstructure

The building was given visual cohesiveness by its principal cladding material, a curtain wall system of glass and stove enamelled sandwich panels (see Fig 11). As an exception, however, in the two-storey carpark and the lower level of the sorting office, closely spaced precast concrete mullion units were incorporated, thus allowing natural ventilation to occur in vehicle movement areas. The roof cladding was a shallow pitch corrugated aluminium system, clipped to supporting members from below, thereby avoiding the need for through fixings and also having the benefit of being free to move thermally.

The final design developed the structural form determined at feasibility stage. In the sorting office the reinforced concrete frame was carried up to first-floor level (see Fig 1) and locally beyond to form the central plantroom. The slab at first-floor level was of conventional solid reinforced concrete construction, 175 mm thick, designed for a superimposed load of 5.5 kN/m² and carried by secondary reinforced concrete beams at 4 m centres. Openings were provided to allow for the installation of chutes and conveyors to take the mails between the sorting office and the receipt and dispatch areas in the loading bays at ground floor. The secondary beams were supported by primary beams normally 1.5 m deep 0.53 m wide, carried to columns on the 12 m grid. However, where the columns were offset in the vehicle movement area at ground floor, the span of the primary beams over was increased to 16 m and their size to 2.5 m by 0.5 m so as to carry the first-floor columns.

In the sorting office the concrete columns continued up to roof level to provide the seating to the structural steel shallow roof pitch of overall dimensions some 73 m 78 m. Provision was made in the bearings at the column heads to accommodate out-of-position tolerances. The external concrete columns were designed as cantilevers against lateral loading. The roof steelwork therefore required no fire protection, since it gave no lateral restraint to the enclosing walls. The steelwork was blast cleaned and then painted with a zinc phosphate epoxy paint system.

Beneath the sorting office roof a steelwork subframe was suspended to carry the mechanical and electrical services (see Fig 12). A further subframe was provided to the side walls to give lateral support to the curtain walling, necessitated by the high head room and wide column spacing.

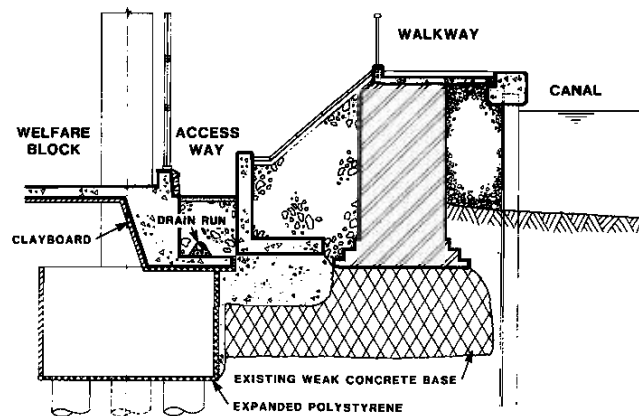

Fig 10. Section through canal wall in heave zone

Fig 11. Canal elevation cladding nearing completion

Fig 12. Services subframe in the sorting office

Fig 13. Canal elevation structural frame nearing completion

In the welfare block, there was conflict between the ideal structural grids for the user and carparking facilities. The lower two floors of carparking were served by ramps. The floors were supported by a grillage of 750 mm \times 1000 mm beams at 4 m centres spanning 12 m onto 900 mm

1500 mm edge beams of similar span. A nominal 175 mm solid concrete slab formed the floor deck with an additional 12 mm concrete thickness as a wearing allowance. The upper floors of the block were of similar framing, but with 200 mm traditional hollow clay pot ribbed slabs. The structural steel roof system was similar to that for the sorting office.

The administration block structural arrangement remained as envisaged at feasibility stage with the slab panels again being formed in hollow pot construction. The top storey comprised a series of steel portal frames (see Fig 13) clad in curtain walling and aluminium roof decking. The reinforcement from the lower columns was carried through into the concrete casing of the portal frame legs to provide stability under fire conditions. This enabled a waiver to be obtained from the Greater London Council against the statutory requirement to provide fire protection to the portal rafters.

The construction

Although the scheme has been with the consultants since January 1980, the Post Office was unable to give instructions to proceed to full design and construction until February 1983. At the same time a completion date was set for June 1985, with the earlier date of March 1985 for the sorting hall so that the letter-sorting machinery could be installed and commissioned. The contract was to be the normal JCT 1980 with Quantities edition. Assessment by the consultants made it clear that, allowing for a 2-year construction period, there was insufficient time available to permit a full design to be completed and normal competitive tenders to be obtained for a start on site in June 1983.

Clearly, early construction would concentrate on overcoming the problems arising from building on a derelict site, many of which would benefit from being worked on during the better weather conditions of the summer months. There was also the requirement to remove the railway embankment at the earliest possible time so that ground movement could take place for as long as possible prior to the permanent works being undertaken. Accordingly, it was decided to run a preliminary contract of 16 weeks' duration for the piling and earthworks, but with stage completion at 12 weeks when sufficient piling would be installed to enable the second and main contractor to commence work.

In recognition of the fact that the majority of the works in the first contract were piling operations, it was decided to offer the work to piling contractors, who would acquire such other support as they deemed

necessary for the general works of breaking out, demolition, and ground excavation. It was intended that, after week 12, the first contract would be assigned to the main contractor who would take on the piling company as his subcontractor with the parties now in their traditional roles.

In accordance with Travers Morgan's normal procedure the piling contractor was required to provide the piles and guarantee their loadcarrying capacity. The piles were to comply with a performance specification based on the consultant's design, compliance being proved by testing in the usual manner. It was during the tender period that the piling contractor, with his advisers, offered an alternative design for the contiguous piles which allowed for 600 mm diameter piles to be spaced at 1 m centres.

The above proposal was accepted and the piling works commenced on time. It was during the early stages that problems from the lack of complete knowledge of the site history and ground conditions manifested themselves. Alongside the Atlantic Metals building the contiguous pile wall was to be installed from the top of the embankment prior to its removal. As the work progressed away from the canal wall, massive masonry construction was discovered which made normal pile boring impossible. The problem was overcome by using a heavy coring machine which enabled an oversize metal liner to be inserted through the masonry into the natural ground and through which the piles were bored and cast.

The intention to monitor ground improvement adjacent to the Atlantic Metals building was put into effect. Inclinometer tubes were installed in three piles at approximately 10 m centres and a baseline was established for reference. Additionally, level pins were fixed to the wall of the building. Monitoring of the inclinometers has shown slight movement of the wall towards the Granary site, but they have not risen, suggesting that the pinning action is successful.

As described, the main bored piling was provided by the piling contractor to a performance specification. A total of 460 piles was proposed, with diameters of 500 mm or 600 mm, having lengths varying from 14 m to 21 m into the clay. The piles were to carry vertical loads in the range of 500 kN to 1700 kN and, additionally, certain of the piles were designed to resist horizontal wind forces of up to 80 kN. Two preliminary load tests were undertaken to prove the design and results from the first test on a 600 mm diameter pile, 21 m long, met the settlement criteria under both working and twice working load. The second test, on a 500 mm diameter pile 14 m long, met the settlement criterion at working load but at twice working load just failed to achieve the appropriate value.

From the two sets of test results it was judged that there had been an overestimation of the cohesion of the upper levels of the clay, and the lengths of the shorter piles were increased by up to 1 m. A further preliminary load test confirmed the adequacy of this revised design. Subsequent tests on working piles also proved satisfactory, these being taken up to 1.5 times working load.

The installation of the working piles was completed successfully, although, as is not uncommon, a few were found to exceed the positional tolerance of 75 mm. Piles designed to resist vertical heave forces required heavy reinforcement cages throughout their full length but, where sleeving was provided over the upper 4 m, the amount was reduced. Since the piling rig was unable to cope with the size and weight of the cages, additional craneage was brought to site.

Forming the annular space to protect the piles from horizontal soil movement was generally straightforward. However, problems were encountered in some areas of made ground where it was necessary to top up the bentonite, presumably because the open nature of the fill provided an initial path for leakage.

Alongside the canal wall the installation of the expanded polystyrene beneath certain pile caps and ground beams presented no problem. However, before placing the much larger quantity of Clayboard under the rest of the construction in that area, precautions were necessary to prevent its premature collapse. This could have occurred from moisture ingress prior to the completion of the permanent concrete works immediately above. The required protection was achieved by sealing the slabs of Clayboard in large polyethylene bags. Tubes were then led from each bag through the concrete slab to enable water to be introduced subsequently into the Clayboard to assist in its collapse.

With the difficulties in the ground overcome, the construction of the superstructure progressed well (see Fig 14) with only occasional problems arising. One of these concerned the contractor's intention to cast the 7m-high columns of the lower storey of the sorting office block in one lift. To facilitate compaction of the concrete the contractor adopted a mix incorporating a superplasticising additive on the advice of a specialist

supplier. However, early results were disappointing, column faces showing signs of excessive bleeding and segregation of the concrete mix. After taking further expert advice the contractor reverted to a standard concrete mix and cast the columns in two lifts.

The concrete for the project was premixed and there was frequent sampling of deliveries. Test cube results, in general, showed 28-day strengths much higher than the specification requirements. Principally, this resulted from the need to incorporate in the mix, for reasons of durability, a larger quantity of cement than was required for strength alone.

Fig 14. Aerial view—superstructure in progress

As soon as the concrete works for the sorting office block had been completed, the erection of the structural steelwork for the roof began. Both the fabrication and the erection of the steelwork might have been expected to present difficulties owing to the complex geometry of parts of the building, particularly the roof. However, the work proceeded uneventfully and the usual concern about the fit between the concrete and steel frames proved unfounded.

The works remain on programme for completion by mid-summer 1985.

Introduction

The Environment Act 1995 has made site sensitivity a key issue, as the legislation pays as much attention to the pathways by which contamination could spread, and to the vulnerable targets of contamination, as it does the potential sources of contamination. For this reason, Landmark's Site Sensitivity maps and Datasheet(s) place great emphasis on statutory data provided by the Environment Agency/Natural Resources Wales and the Scottish Environment Protection Agency; it also incorporates data from Natural England (and the Scottish and Welsh equivalents) and Local Authorities; and highlights hydrogeological features required by environmental and geotechnical consultants. It does not include any information concerning past uses of land. The datasheet is produced by querying the Landmark database to a distance defined by the client from a site boundary provided by the client.

In the attached datasheet the National Grid References (NGRs) are rounded to the nearest 10m in accordance with Landmark's agreements with a number of Data Suppliers.
