Appendix B – Site Plan and Monitoring Positions

Appendix C – PM10 Working Day Daily Maximum Levels

1.0 Introduction

Demolition and construction works are due to take place at Network Building, 95-100 Tottenham Court Road.

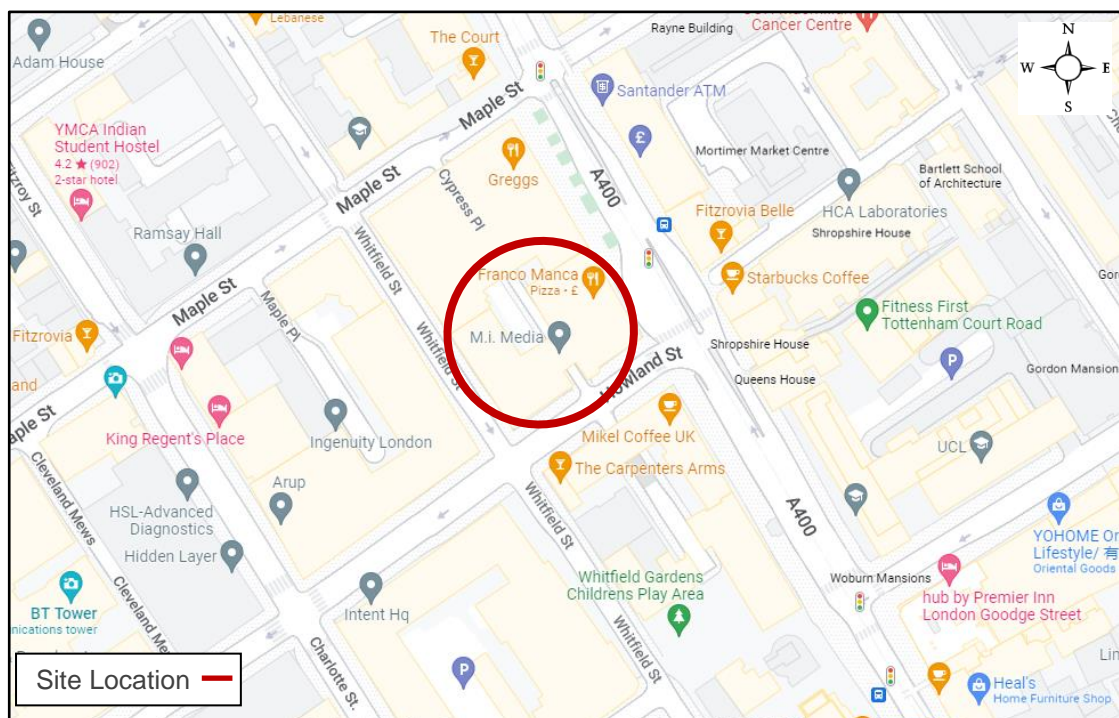

Hann Tucker Associates have been appointed to undertake unmanned air particulate (dust) monitoring at Network Building, 95-100 Tottenham Court Road, in order to establish the baseline dust levels prior to the commencement of project works at the aforementioned site.

This report presents the procedures employed for the monitoring and the data obtained during the baseline monitoring period spanning 24 March 2022 to 23 June 2022.

2.0 Site Description

2.1 Location

The site is located at 95-100 Tottenham Court Road and falls within the jurisdiction of Camden London Borough Council. See Location Map below.

Location Map (Map data ©Google)

2.2 Description

Network Building, 95-100 Tottenham Court Road is situated approximately halfway between Goodge Street and Warren Street tube stations. The current building comprises 6No. storeys, mostly used as office and retail space. The plan is to demolish the existing building to replace it with a 9No. storey modern commercial building, which includes contemporary office space and high-quality retail space fronting Tottenham Court Road. The surrounding area contains a mixture of building type, including residential buildings, offices, restaurants, retail space and banks.

Site Plan (Imagery ©2022 Bluesky, Getmapping Plc, Infoterra & Bluesky, MAXar Technologies, The Geoinformation Group. Map data ©2022 Google)

3.0 Methodology

3.1 Equipment

Electronic automated air particle monitors were installed at the development site, and were continuously maintained, since 24 March 2022.

The airborne particle monitoring instruments use proprietary nephelometers, where a pump continuously draws an air sample through the nephelometer which analyses the individual particles as they pass through a laser beam. These same particles are then collected on the reference filter.

The airborne particle monitors are sensitive to airborne particle concentrations down to a fraction of a microgram per cubic metre and the dedicated microprocessor can analyse individual particles even if there are millions per litre. This allows size fractions to be determined at concentrations up to several $\mu\text{g}/\text{m}^3$. Above this level there is an indicator range which can be used without sizing up to $60\mu\text{g}/\text{m}^3$.

The instruments feature internal data logging for the particle concentrations.

The following equipment was used for the baseline monitoring:

- 2No. Turnkey OSIRIS Monitors.

Each air particle meter was located in an environmental case.

3.2 Procedure

Fully automated air particle measurements were undertaken from 24 March 2022 to 23 June 2022.

The airborne particle monitors measure and report information for total, $10\mu\text{m}$, $2.5\mu\text{m}$ and $1\mu\text{m}$ size particles. The units have been set to sample continuously and present 15-minute average readings.

3.3 Measurement Positions

The air particle measurements were undertaken at 2No. positions as described in the table below and shown in on the site plan in Appendix B.

Position No	Description
1	The monitor was located approximately 4m above ground-level, towards the south-west of the existing structure. The monitor was fixed to the masonry of 78 Whitfield Street via a metal bracket, which extended approximately 0.5m from the façade of the building. This position was chosen to best represent the dust levels experienced by receptors to the south and west of the development.
2	The monitor was located approximately 4m above ground-level, towards the north-east corner of the existing structure. The monitor was fixed to the masonry above the retail unit for Pret-A-Manger via a metal bracket, which extended approximately 0.5m from the façade of the building. This position was chosen to best represent the dust levels experienced by receptors to the north and east of the development.

Each air particle monitor was calibrated prior to the commencement of monitoring. This calibration is regularly checked and maintained by the equipment manufacturer.

4.0 Results

The measured 15-minute mean PM10 concentration levels are presented on the enclosed Time History Graphs 29704/ATH1.1 – 28294/ATH1.6.

The maximum measured 15-minute mean PM10 concentration levels during site working hours are presented within Appendix C.

5.0 Discussion

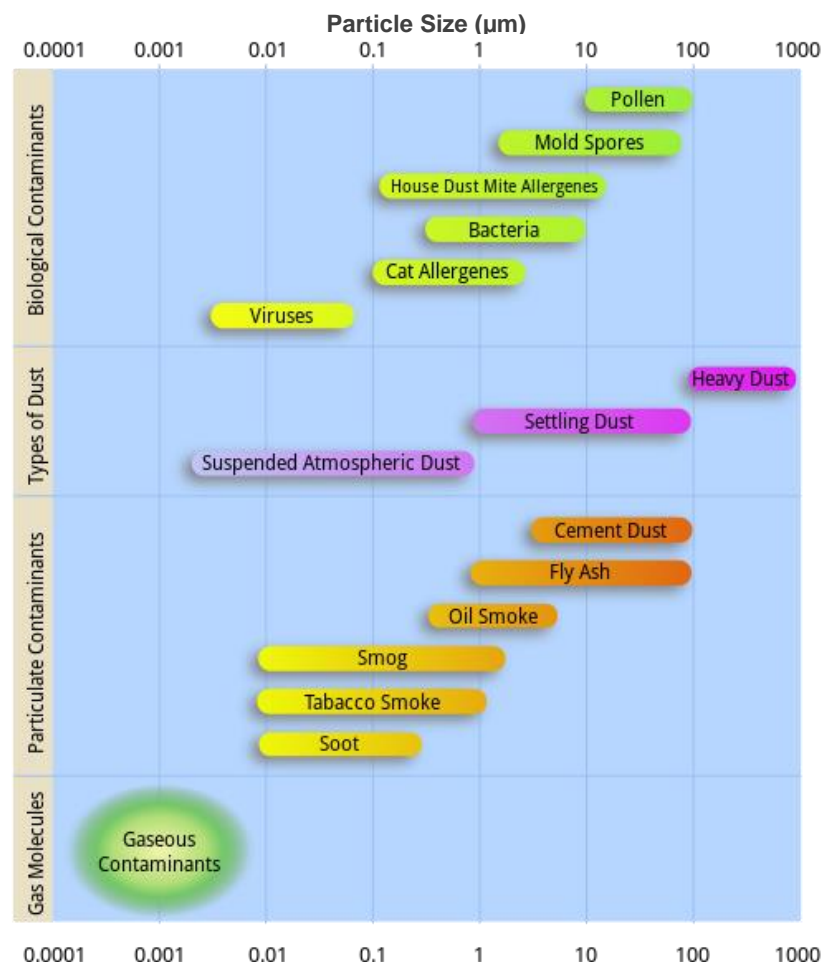

Baseline air particle monitoring has been undertaken at Network Building, 95-100 Tottenham Court Road during the period of 24 March 2022 to 23 June 2022.

The results are presented herein.

Appendix A – Air Particle Monitoring Terminology

PM_x

Particulate Matter - Used as a measurement of air particles where x is the size of the particle measured in micrometres (or μm). PM₁₀ describes inhalable particles, with diameters that are 10 micrometres and smaller. Sources include crushing or grinding operations and dust stirred up by vehicles on roads. PM_{2.5} describes fine particles that are 2.5 micrometres or smaller in diameter and can only be seen with an electron microscope and are able to penetrate to the lungs. Typical sources include all types of combustion, including motor vehicles, power plants and agricultural burning. PM₁ describes particles that are 1 micrometre or smaller in diameter. The diagram below shows common airborne particles and their typical sizes along the PM scale.

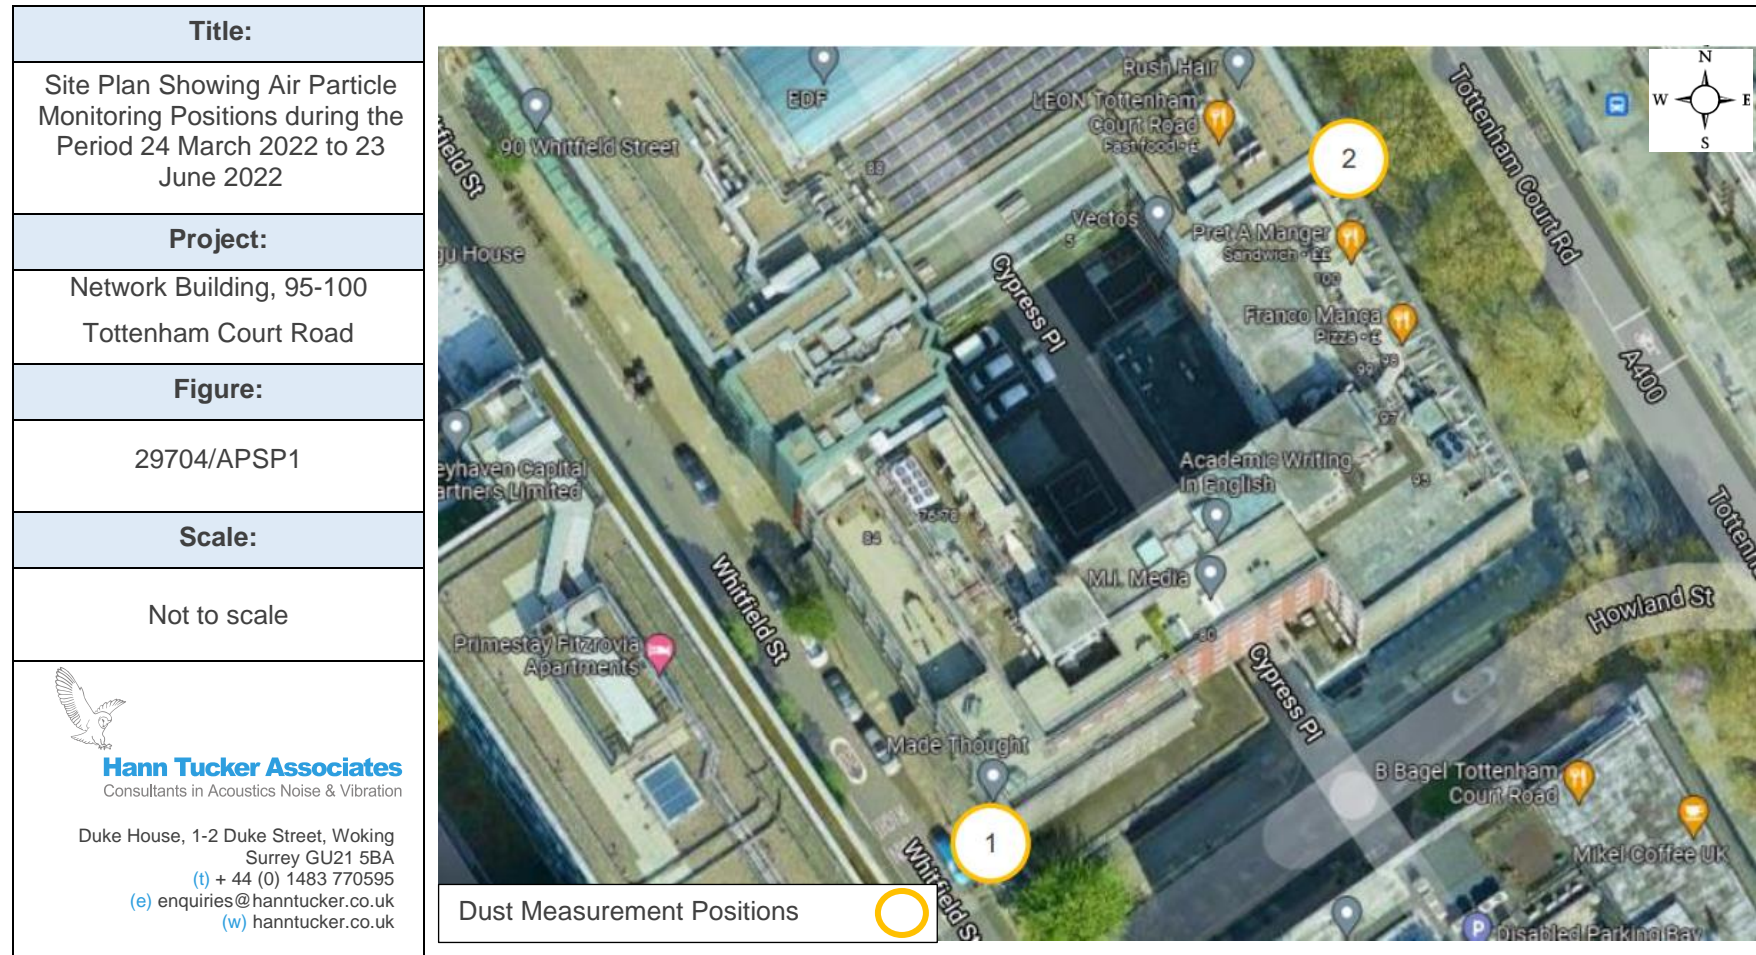

TSP

Total Suspended Particles - Used as a measure of the mass concentration of particulate matter in the air. TSP covers the full range of particle sizes and is commonly measured alongside PM₁₀ and PM_{2.5}.

Nephelometer	Sometimes referred to as a turbidimeter, these devices are used to measure the concentration of particulates suspended in a fluid. Suspended particulates are measured by employing a light beam and a light detector set to one side (often 90°) of the source beam. Particle density is then a function of the light reflected into the detector from the particles.
Anemometer	Device used for measuring wind speed and direction. Three-cup anemometers, consisting of three hemispherical cups mounted horizontally on a vertical shaft, are currently used as the industry standard for wind resource assessment studies and practice.

Appendix B – Site Plan and Monitoring Positions

Appendix C – Maximum Measured 15-Minute Mean PM10 Concentration

The following table presents the maximum 15-minute mean PM10 levels measured during typical site working hours (08:00-18:00) for each of the 2No. positions around the development site during the period 24 March 2022 to 23 June 2022.

Date	Maximum Measured 15-Minute Mean PM10 Concentration (µg/m³)	
	Position 1	Position 2
Thursday 24 March 2022	28.0	61.7
Friday 25 March 2022	120.3	116.1
Saturday 26 March 2022	56.6	56.3
Sunday 27 March 2022	19.9	23.7
