#### INTRODUCTION

This schedule of works is has been completed for pricing of the masonry repair works to the east and west residence stairs. It is to be read in conjunction with Alan Baxter's drawings and specification for structural repairs of the stairs and Dannatt, Johnson Specification for the works Ref:

Site inspection works were carried out between the 17<sup>th</sup> and 18<sup>th</sup> November 2022. Weather generally cloudy and temperatures in the region of 12°C.

Inspections were carried out by: Jonathan Parry Jessica Wheeler.

## LIMITATIONS

No exploratory or opening up works were carried out as part of the survey.

No high level access was provides the survey was carried out from floor levels only.

Comments on services are for information only testing needs to be completed to determine if the installations affected are live.

### **GENERAL COMMENTS**

Main stairs 2, 4, 6, 8 & 9 are covered on the top faces by what appears to be a cementitious screed with large aggregates to form a slip resistant surface. The likelihood is that this has been installed to repair damage, wear and decay to the top surfaces of what are noted on the available historic drawings as Portland stone steps.

Without removal of the finish the condition of the upper surface of the stone steps cannot be determined. The cementitious screed will also seal the face of the existing stone preventing any trapped moisture from evaporating through the top surface. The screed itself is in reasonable condition although some cracking was noted that would allow water through to the stone. The bottom tread of stair 4 is has a repair to the screed made in general mortar without the non-slip aggregate.

Except for stairs 4 and 6 the junction of the finishing screed to the stone baluster perimeter is unsealed and provides a potential path for water through the steps and the flanking structure. Stair 4 has failing 40-50mm cementitious fillets in these locations while stair 6 has a neater and mainly intact 10mm fillet finish. The condition of the pointing to the stairs (see item 042) is showing failure at junctions with fillet opening up and letting water into the construction. The removal of the cementitious finish has been reviewed with the British Museum and structural engineer. In removing the existing cementitious topping there would be a high risk of further damage to the base stone steps which could require replacement of the step impact on electrical and fire alarm services that are supported on the undersides of the stairs.

For the purpose of this report and the proposed repairs, the risk of further damage to the base stone, are considered to be too great in respect of the removal of the cementitious topping.

Recommended works are to leave the toppings in place and reduce the potential for letting water into the construction through repair of cracks and forming a regular 10mm chase in the cementitious finish and seal with new pointing at all tread riser junctions and at the perimeter of the steps.

In some locations the undersides of these stairs show repairs in concrete materials, which like the surface prevent natural evaporation of moisture contained within the stones. The majority of the undersides of these stairs show stone decay and spalling probably caused by freezing of trapped water and salt crystallisation behind the surface. The cementitious material used on the top surfaces forcing moisture to migrate to wards the lower faces probably exacerbates the decay on the rear faces. In areas this is prevented from evaporating by painted surfaces most of which are failing.

Stairs 3 and 5 are in the worst condition. Of the flanking staircases to the residences, stair 3 is the last remaining example of the original stone tread and wrought iron railing.

Efforts should be made to repair and conserve this. Repairs to stair 3 will be the subject of a separate LBC application.

Stair 5 is constructed from reinforced concrete, the repairs required for this and additional steel supports are documented in the structural engineers report.

Without the removal of the impervious cementitious screed finishes which may cause further damage to the steps and possibly require their replacement we can only hope to slow the decay of the stone by removing routes for new water to enter the structures from the top surface and promoting natural drying and evaporation from the undersides through improved ventilation where possible, removing impervious finishes and repairs that are trapping moisture. We recommend a review to include electric radiators to provide trace heating in covered under stair spaces to prevent freeze thaw action. It may also be worth considering a sacrificial breathable lime render layer to the underside of the steps although in a sheltered location this may not work effectively so we suggest trialling it in one of the more accessible areas.

Generally for works around the stairs including the flanking walls and balustrades we recommend removal of impervious applied finishes to promote the drying out of these areas and following paint removal inspection of the exposed brickwork and mortar joints and to ensure any remedial repairs using lime mortars can be carried out. Our preference would be to leave the walls as natural finish on completion however where this is not possible a breathable finish to be applied such as lime wash or a mineral paint such as Keim in more heavily trafficked areas.
